

Notes from the editor:

- The book was scanned and converted (via O.C.R.) by one person and edited by another (using an IBM PC compatible), independently.
- All pages have a fix size of 64 lines. The width was not justified to make future modifications easier, though no line is longer than 80 columns.
- This book only covers standard MSX. The BIOS entry points from 0000H to 01B5H should be used instead of the called entries described in the book, because other machines (MSX2, MSX2+, MSX turbo R and customized ones) have different positions for the routines. The use of internal BIOS routine addresses are responsible for many programs only running in MSX.
- Some errors present in the original book were fixed, though it was tried to keep it as unaltered as possible. All page numbers match the originals, except undetected errors already present in the original.
- Most figures were modiflicated due to the text-only nature of this file. The character set used during edition was the International IBM PC's one. The following special characters were used and should be changed to the corresponding ones of other character sets:

Frame	ÚÄÄÄ;	Pound: œ
characters:	³ ³ ³	Micro: æ
	ÄÄÄÄ´	
	³ ³ ³	
	ÄÄÄÄÙ

INTRODUCTION

Aims

This book is about MSX computers and how they work. For technical and commercial reasons MSX computer manufacturers only make a limited amount of information available to the end user about the design of their machines. Usually this will be a fairly detailed description of Microsoft MSX BASIC together with a broad outline of the system hardware. While this level of documentation is adequate for the casual user it will inevitably prove limiting to anyone engaged in more sophisticated programming.

The aim of this book is to provide a description of the standard MSX hardware and software at a level of detail sufficient to satisfy that most demanding of users, the machine code programmer. It is not an introductory course on programming and is necessarily of a rather technical nature. It is assumed that you already possess, or intend to acquire by other means, an understanding of the Z80 Microprocessor at the machine code level. As there are so many general purpose books already in existence about the Z80 any description of its characteristics would simply duplicate widely available information.

Organization

The MSX Standard specifies the following as the major functional components in any MSX computer:

- (1) Zilog Z80 Microprocessor
- (2) Intel 8255 Programmable Peripheral Interface
- (3) Texas 9929 Video Display Processor
- (4) General Instrument 8910 Programmable Sound Generator
- (5) 32 KB MSX BASIC ROM
- (6) 8 KB RAM minimum

Although there are obviously a great many additional components involved in the design of an MSX computer they are all small-scale, non-programmable ones and therefore "invisible" to the user. Manufacturers generally have considerable freedom in the selection of these small-scale components. The programmable components cannot be varied and therefore all MSX machines are identical as far as the programmer is concerned.

Chapters 1, 2 and 3 describe the operation of the Programmable Peripheral Interface, Video Display Processor and Programmable Sound Generator respectively. These three devices

INTRODUCTION

provide the interface between the Z80 and the peripheral hardware on a standard MSX machine. All occupy positions on the Z80 I/O (Input/output) Bus.

Chapter 4 covers the software contained in the first part of the MSX ROM. This section of the ROM is concerned with controlling the machine hardware at the fine detail level and is known as the ROM BIOS (Basic Input Output System). It is structured in such a way that most of the functions a machine code programmer requires, such as keyboard and video drivers, are readily available.

Chapter 5 describes the software contained in the remainder of the ROM, the Microsoft MSX BASIC Interpreter. Although this is largely a text-driven program, and consequently of less use to the programmer, a close examination reveals many points not documented by manufacturers.

Chapter 6 is concerned with the organization of system memory. Particular attention is paid to the Workspace Area, that section of RAM from F380H to FFFFH, as this is used as a scratchpad by the BIOS and the BASIC Interpreter and contains much information of use to any application program.

Chapter 7 gives some examples of machine code programs that make use of ROM features to minimize design effort.

It is believed that this book contains zero defects, if you know otherwise the author would be delighted to hear from you. This book is dedicated to the Walking Nightmare.

1. PROGRAMMABLE PERIPHERAL INTERFACE

The 8255 PPI is a general purpose parallel interface device configured as three eight bit data ports, called A, B and C, and a mode port. It appears to the Z80 as four I/O ports through which the keyboard, the memory switching hardware, the cassette motor, the cassette output, the Caps Lock LED and the Key Click audio output can be controlled. Once the PPI has been initialized access to a particular piece of hardware just involves writing to or reading the relevant I/O port.

PPI Port A (I/O Port A8H)

Figure 1: Primary Slot Register

This output port, known as the Primary Slot Register in MSX terminology, is used to control the memory switching hardware. The Z80 Microprocessor can only access 64 KB of memory directly. This limitation is currently regarded as too restrictive and several of the newer personal computers employ methods to overcome it.

MSX machines can have multiple memory devices at the same address and the Z80 may switch in any one of them as required. The processor address space is regarded as being duplicated "sideways" into four separate 64 KB areas, called Primary Slots 0 to 3, each of which receives its own slot select signal alongside the normal Z80 bus signals. The contents of the Primary Slot Register determine which slot select signal is active and therefore which Primary Slot is selected.

To increase flexibility each 16 KB "page" of the Z80 address space may be selected from a different Primary Slot. As shown in Figure 1 two bits of the Primary Slot Register are required to define the Primary Slot number for each page.

The first operation performed by the MSX ROM at power-up is to search through each slot for RAM in pages 2 and 3 (8000H to FFFFH). The Primary Slot Register is then set so that the relevant slots are selected thus making the RAM permanently available. The memory configuration of any MSX machine can be

1. PROGRAMMABLE PERIPHERAL INTERFACE

determined by displaying the Primary Slot Register setting with the BASIC statement:

```
PRINT RIGHT$("0000000"+BIN$(INP(&HA8)),8)
```

As an example "10100000" would be produced on a Toshiba HX10 where pages 3 and 2 (the RAM) both come from Primary Slot 2 and pages 1 and 0 (the MSX ROM) from Primary Slot 0. The MSX ROM must always be placed in Primary Slot 0 by a manufacturer as this is the slot selected by the hardware at power-up. Other memory devices, RAM and any additional ROM, may be placed in any slot by a manufacturer.

A typical UK machine will have one Primary Slot containing the MSX ROM, one containing 64 KB of RAM and two slots brought out to external connectors. Most Japanese machines have a cartridge type connector on each of these external slots but UK machines usually have one cartridge connector and one IDC connector.

Expanders

System memory can be increased to a theoretical maximum of sixteen 64 KB areas by using expander interfaces. An expander plugs into any Primary Slot to provide four 64 KB Secondary Slots, numbered 0 to 3, instead of one primary one. Each expander has its own local hardware, called a Secondary Slot Register, to select which of the Secondary Slots should appear in the Primary Slot. As before pages can be selected from different Secondary Slots.

7	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	0	0
3	3	3	3	3	3	3	3	3
3	3	3	3	3	3	3	3	3
0	0	0	0	0	0	0	0	0

Figure 2: Secondary Slot Register

Each Secondary Slot Register, while actually being an eight bit read/write latch, is made to appear as memory location FFFFH of its Primary Slot by the expander hardware. In order to gain access to this location on a particular expander it will usually be necessary to first switch page 3 (C000H to FFFFH) of that Primary Slot into the processor address space. The Secondary Slot Register can then be modified and, if necessary, page 3 restored to its original Primary Slot setting. Accessing memory in expanders can become rather a convoluted process.

It is apparent that there must be some way of determining whether a Primary Slot contains ordinary RAM or an expander in

1. PROGRAMMABLE PERIPHERAL INTERFACE

order to access it properly. To achieve this the Secondary Slot Registers are designed to invert their contents when read back. During the power-up RAM search memory location FFFFH of each Primary Slot is examined to determine whether it behaves normally or whether the slot contains an expander. The results of these tests are stored in the Workspace Area system resource map EXPTBL for later use. This is done at power-up because of the difficulty in performing tests when the Secondary Slot Registers actually contain live settings.

Memory switching is obviously an area demanding extra caution, particularly with the hierarchical mechanisms needed to control expanders. Care must be taken to avoid switching out the page in which a program is running or, if it is being used, the page containing the stack. There are a number of standard routines available to the machine code programmer in the BIOS section of the MSX ROM to simplify the process.

The BASIC Interpreter itself has four methods of accessing extension ROMs. The first three of these are for use with machine code ROMs placed in page 1 (4000H to 7FFFH), they are:

- (1) Hooks (Chapter 6).
- (2) The "CALL" statement (Chapter 5).
- (3) Additional device names (Chapter 5).

The BASIC Interpreter can also execute a BASIC program ROM detected in page 2 (8000H to BFFFH) during the power-up ROM search. What the BASIC Interpreter cannot do is use any RAM hidden behind other memory devices. This limitation is a reflection of the difficulty in converting an established program to take advantage of newer, more complex machines. A similar situation exists with the version of Microsoft BASIC available on the IBM PC. Out of a 1 MB memory space only 64 KB can be used for program storage.

PPI Port B (I/O Port A9H)

Figure 3

This input port is used to read the eight bits of column data from the currently selected row of the keyboard. The MSX keyboard is a software scanned eleven row by eight column matrix of normally open switches. Current machines usually only have keys in rows zero to eight. Conversion of key depressions

1. PROGRAMMABLE PERIPHERAL INTERFACE

into character codes is performed by the MSX ROM interrupt handler, this process is described in Chapter 4.

PPI Port C (I/O Port AAH)

Figure 4

This output port controls a variety of functions. The four Keyboard Row Select bits select which of the eleven keyboard rows, numbered from 0 to 10, is to be read in by PPI Port B.

The Cas Motor bit determines the state of the cassette motor relay: 0=On, 1=Off.

The Cas Out bit is filtered and attenuated before being taken to the cassette DIN socket as the MIC signal. All cassette tone generation is performed by software.

The Cap LED bit determines the state of the Caps Lock LED: 0=On, 1=Off.

The Key Click output is attenuated and mixed with the audio output from the Programmable Sound Generator. To actually generate a sound this bit should be flipped on and off.

Note that there are standard routines in the ROM BIOS to access all of the functions available with this port. These should be used in preference to direct manipulation of the hardware if at all possible.

PPI Mode Port (I/O Port ABH)

Figure 5: PPI Mode Selection

This port is used to set the operating mode of the PPI. As the MSX hardware is designed to work in one particular

1. PROGRAMMABLE PERIPHERAL INTERFACE

configuration only this port should not be modified under any circumstances. Details are given for completeness only.

Bit 7 must be 1 in order to alter the PPI mode, when it is 0 the PPI performs the single bit set/reset function shown in Figure 6.

The A&C Mode bits determine the operating mode of Port A and the upper four bits only of Port C: 00=Normal Mode (MSX), 01=Strobed Mode, 10=Bidirectional Mode

The A Dir mode determines the direction of Port A: 0=Output (MSX), 1=Input.

The C Dir bit determines the direction of the upper four bits only of Port C: 0=Output (MSX), 1=Input.

The B&C Mode bits determine the operating mode of Port B and the lower four bits only of Port C: 0=Normal Mode (MSX), 1=Strobed Mode.

The B Dir bit determines the direction of Port B:0= output, 1=Input (MSX).

The C Dir bit determines the direction of the lower four bits only of Port C: 0=Output (MSX), 1=Input

Figure 6: PPI Bit Set/Reset

The PPI Mode Port can be used to directly set or reset any bit of Port C when bit 7 is 0. The Bit Number, from 0 to 7, determines which bit is to be affected. Its new value is determined by the Set/Reset bit: 0=Reset, 1=Set. The advantage of this mode is that a single output can be easily modified. As an example the Caps Lock LED may be turned on with the BASIC statement OUT &HAB,12 and off with the statement OUT &HAB,13.

2. VIDEO DISPLAY PROCESSOR

synchronization. The MSX ROM interrupt handler is continuously reading the VDP Status Register as a background task so interrupts should be disabled as necessary.

VDP Status Register

Reading the Command Port will input the contents of the VDP Status Register. This contains various flags as below:

Figure 8: VDP Status Register

The Fifth Sprite Number bits contain the number (0 to 31) of the sprite triggering the Fifth Sprite Flag.

The Coincidence Flag is normally 0 but is set to 1 if any sprites have one or more overlapping pixels. Reading the Status Register will reset this flag to a 0. Note that coincidence is only checked as each pixel is generated during a video frame, on a UK machine this is every 20 ms. If fast moving sprites pass over each other between checks then no coincidence will be flagged.

The Fifth Sprite Flag is normally 0 but is set to 1 when there are more than four sprites on any pixel line. Reading the Status Register will reset this flag to a 0.

The Frame Flag is normally 0 but is set to a 1 at the end of the last active line of the video frame. For UK machines with a 50 Hz frame rate this will occur every 20 ms. Reading the Status register will reset this flag to a 0. There is an associated output signal from the VDP which generates Z80 interrupts at the same rate, this drives the MSX ROM interrupt handler.

VDP Mode Registers

The VDP has eight write-only registers, numbered 0 to 7, which control its general operation. A particular register is set by first writing a data byte then a register selection byte to the Command Port. The register selection byte contains the register number in the lower three bits: 1000RRR. As the Mode Registers are write-only, and cannot be read, the MSX ROM maintains an exact copy of the eight registers in the Workspace Area of RAM (Chapter 6). Using the MSX ROM standard routines for VDP functions ensures that this register image is correctly updated.

2. VIDEO DISPLAY PROCESSOR

Mode Register 0

Figure 9

The External VDP bit determines whether external VDP input is to be enabled or disabled: 0=Disabled, 1=Enabled.

The M3 bit is one of the three VDP mode selection bits, see Mode Register 1.

Mode Register 1

Figure 10

The Magnification bit determines whether sprites will be normal or doubled in size: 0=Normal, 1=Doubled.

The Size bit determines whether each sprite pattern will be 8x8 bits or 16x16 bits: 0=8x8, 1=16x16.

The M1 and M2 bits determine the VDP operating mode in conjunction with the M3 bit from Mode Register 0:

M1	M2	M3	
0	0	0	32x24 Text Mode
0	0	1	Graphics Mode
0	1	0	Multicolour Mode
1	0	0	40x24 Text Mode

The Interrupt Enable bit enables or disables the interrupt output signal from the VDP: 0=Disable, 1=Enable.

The Blank bit is used to enable or disable the entire video display: 0=Disable, 1=Enable. When the display is blanked it will be the same colour as the border.

The 4/16K bit alters the VDP VRAM addressing characteristics to suit either 4 KB or 16 KB chips: 0=4 KB, 1=16 KB.

2. VIDEO DISPLAY PROCESSOR

Mode Register 5

Figure 14

Mode Register 5 defines the starting address of the Sprite Attribute Table in the VDP VRAM. The seven available bits only specify positions 00BB BBBB B000 0000 of the full address so register contents of 7FH would result in a base address of 3F80H.

Mode Register 6

Figure 15

Mode Register 6 defines the starting address of the Sprite Pattern Table in the VDP VRAM. The three available bits only specify positions 00BB B000 0000 0000 of the full address so register contents of 07H would result in a base address of 3800H.

Mode Register 7

Figure 16

The Border Colour bits determine the colour of the region surrounding the active video area in all four VDP modes. They also determine the colour of all 0 pixels on the screen in 40x24 Text Mode. Note that the border region actually extends across the entire screen but will only become visible in the active area if the overlying pixel is transparent.

2. VIDEO DISPLAY PROCESSOR

The Text Colour 1 bits determine the colour of all 1 pixels in 40x24 Text Mode. They have no effect in the other three modes where greater flexibility is provided through the use of the Colour Table. The VDP colour codes are:

0 Transparent	4 Dark Blue	8 Red	12 Dark Green
1 Black	5 Light Blue	9 Bright Red	13 Purple
2 Green	6 Dark Red	10 Yellow	14 Grey
3 Light Green	7 Sky Blue	11 Light Yellow	15 White

Screen Modes

The VDP has four operating modes, each one offering a slightly different set of capabilities. Generally speaking, as the resolution goes up the price to be paid in VRAM size and updating complexity also increases. In a dedicated application these associated hardware and software costs are important considerations. For an MSX machine they are irrelevant, it therefore seems a pity that a greater attempt was not made to standardize on one particular mode. The Graphics Mode is capable of adequately performing all the functions of the other modes with only minor reservations.

An added difficulty in using the VDP arises because insufficient allowance was made in its design for the overscanning used by most televisions. The resulting loss of characters at the screen edges has forced all the video-related MSX software into being based on peculiar screen sizes. UK machines normally use only the central thirty-seven characters available in 40x24 Text Mode. Japanese machines, with NTSC (National Television Standards Committee) video outputs, use the central thirty-nine characters.

The central element in the VDP, from the programmer's point of view, is the Name Table. This is a simple list of single-byte character codes held in VRAM. It is 960 bytes long in 40x24 Text Mode, 768 bytes long in 32x24 Text Mode, Graphics Mode and Multicolour Mode. Each position in the Name Table corresponds to a particular location on the screen.

During a video frame the VDP will sequentially read every character code from the Name Table, starting at the base. As each character code is read the corresponding 8x8 pattern of pixels is looked up in the Character Pattern Table and displayed on the screen. The appearance of the screen can thus be modified by either changing the character codes in the Name Table or the pixel patterns in the Character Pattern Table.

Note that the VDP has no hardware cursor facility, if one is required it must be software generated.

2. VIDEO DISPLAY PROCESSOR

2000H to 37FFH. There is an exact byte-to-byte mapping from the Character Pattern Table to the Colour Table but, because it takes a whole byte to define the 0 pixel and 1 pixel colours, there is a lower resolution for colours than for pixels. The lower four bits of a Colour Table entry define the colour of all the 0 pixels on the corresponding eight pixel line. The upper four bits define the colour of the 1 pixels. The Colour Table is initialized so that the 0 pixel colour and the 1 pixel colour are blue for the entire table. Because both colours are the same it will be necessary to alter one colour when a bit is set in the Character Pattern Table.

Multicolour Mode

The Name Table occupies 768 bytes of VRAM from 0800H to 0AFFH, the screen mapping is the same as in 32x24 Text Mode. The table is initialized with the following character code pattern:

00H to 1FH (Repeated four times)
 20H to 3FH (Repeated four times)
 40H to 5FH (Repeated four times)
 60H to 7FH (Repeated four times)
 80H to 9FH (Repeated four times)
 A0H to BFH (Repeated four times)

As with Graphics Mode this is just a character code "driver" pattern, it is the Character Pattern Table which is modified during normal operation.

The Character Pattern table occupies 1536 bytes of VRAM from 0000H to 05FFH. As in the other modes each character code maps onto an eight byte block in the Character Pattern Table. Because of the lower resolution in this mode only two bytes of the pattern block are actually needed to define an 8x8 pattern:

ÚÄÄÄÄÄÄÄÄÄÄÄÄÄÄÄÄÄ¸		ÚÄÄÄÄÄÄÄ¸
³A A A A B B B B³ Byte 0		³ ³ ³
³C C C C D D D D³ Byte 1		³ A ³ B ³
³³³		³ ³ ³
³		ÄÄÄÄÄÄÄÄ´
³		³ ³ ³
³		³ C ³ D ³
ÄÄÄÄÄÄÄÄÄÄÄÄÄÄÄÄÙ		³ ³ ³
		ÄÄÄÄÄÄÄÄÙ

Figure 21: Multicolour Pattern Block

As can be seen from Figure 21 each four bit section of the two byte block contains a colour code and thus defines the COLOUR of a quadrant of the 8x8 pixel pattern. So that the entire eight bytes of the pattern block can be utilized a given character code will use a different two byte section depending

2. VIDEO DISPLAY PROCESSOR

1B00H to 1B7FH. The table contains thirty-two four byte blocks, one for each sprite. The first block controls sprite 0 (the "top" sprite), the second controls sprite 1 and so on to sprite 31. The format of each block is as below:

```

   7 6 5 4 3 2 1 0
UAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA;
 3   Vertical Position   3 Byte 0
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA'
 3   Horizontal Position 3 Byte 1
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA'
 3   Pattern Number      3 Byte 2
AAââââââââââââââââââââââââââââââââââ'
3EC 3 0 3 0 3 0 3   Colour Code 3 Byte 3
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAU

```

Figure 23: Sprite Attribute Block

Byte 0 specifies the vertical (Y) coordinate of the top-left pixel of the sprite. The coordinate system runs from -1 (FFH) for the top pixel line on the screen down to 190 (BEH) for the bottom line. Values less than -1 can be used to slide the sprite in from the top of the screen. The exact values needed will obviously depend upon the size of the sprite. Curiously there has been no attempt in MSX BASIC to reconcile this coordinate system with the normal graphics range of Y=0 to 191. As a consequence a sprite will always be one pixel lower on the screen than the equivalent graphic point. Note that the special vertical coordinate value of 208 (D0H) placed in a sprite attribute block will cause the VDP to ignore all subsequent blocks in the Sprite Attribute Table. Effectively this means that any lower sprites will disappear from the screen.

Byte 1 specifies the horizontal (X) coordinate of the top-left pixel of the sprite. The coordinate system runs from 0 for the leftmost pixel to 255 (FFH) for the rightmost. As this coordinate system provides no mechanism for sliding a sprite in from the left a special bit in byte 3 is used for this purpose, see below.

Byte 2 selects one of the two hundred and fifty-six 8x8 bit patterns available in the Sprite Pattern Table. If the Size bit is set in VDP Mode Register 1, resulting in 16x16 bit patterns occupying thirty-two bytes each, the two least significant bits of the pattern number are ignored. Thus pattern numbers 0, 1, 2 and 3 would all select pattern number 0.

In Byte 3 the four Colour Code bits define the colour of the 1 pixels in the sprite patterns, 0 pixels are always

2. VIDEO DISPLAY PROCESSOR

transparent. The Early Clock bit is normally 0 but will shift the sprite thirty-two pixels to the left when set to 1. This is so that sprites can slide in from the left of the screen, there being no spare coordinates in the horizontal direction.

The Sprite Pattern Table occupies 2 KB of VRAM from 3800H to 3FFFH. It contains two hundred and fifty-six 8x8 pixel patterns, numbered from 0 to 255. If the Size bit in VDP Mode Register 1 is 0, resulting in 8x8 sprites, then each eight byte sprite pattern block is structured in the same way as the character pattern block shown in Figure 18. If the Size bit is 1, resulting in 16x16 sprites, then four eight byte blocks are needed to define the pattern as below:

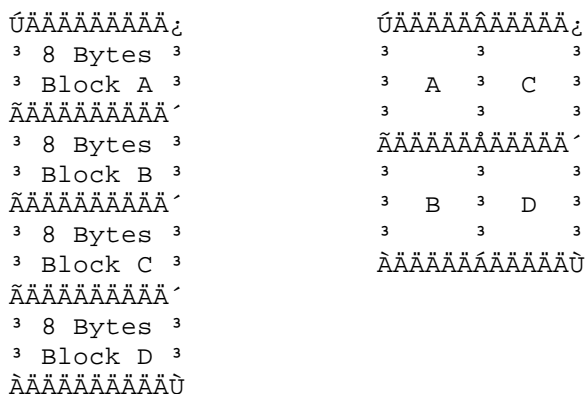

Figure 24: 16x16 Sprite Pattern Block

3. PROGRAMMABLE SOUND GENERATOR

As well as controlling three sound channels the 8910 PSG contains two eight bit data ports, called A and B, through which it interfaces the joysticks and the cassette input. The PSG appears to the Z80 as three I/O ports called the Address Port, the Data Write Port and the Data Read Port.

Address Port (I/O port A0H)

The PSG contains sixteen internal registers which completely define its operation. A specific register is selected by writing its number, from 0 to 15, to this port. Once selected, repeated accesses to that register may be made via the two data ports.

Data Write Port (I/O port A1H)

This port is used to write to any register once it has been selected by the Address Port.

Data Read Port (I/O port A2H)

This port is used to read any register once it has been selected by the Address Port.

Registers 0 and 1

Figure 25

These two registers are used to define the frequency of the Tone Generator for Channel A. Variable frequencies are produced by dividing a fixed master frequency with the number held in Registers 0 and 1, this number can be in the range 1 to 4095. Register 0 holds the least significant eight bits and Register 1 the most significant four. The PSG divides an external 1.7897725 MHz frequency by sixteen to produce a Tone Generator master frequency of 111,861 Hz. The output of the Tone Generator

3. PROGRAMMABLE SOUND GENERATOR

can therefore range from 111,861 Hz (divide by 1) down to 27.3 Hz (divide by 4095). As an example to produce a middle "A" (440 Hz) the divider value in Registers 0 and 1 would be 254.

Registers 2 and 3

These two registers control the Channel B Tone Generator as for Channel A.

Registers 4 and 5

These two registers control the Channel C Tone Generator as for Channel A.

Register 6

Figure 26

In addition to three square wave Tone Generators the PSG contains a single Noise Generator. The fundamental frequency of the noise source can be controlled in a similar fashion to the Tone Generators. The five least significant bits of Register 6 hold a divider value from 1 to 31. The Noise Generator master frequency is 111,861 Hz as before.

Register 7

Figure 27

This register enables or disables the Tone Generator and Noise Generator for each of the three channels: 0=Enable 1=Disable. It also controls the direction of interface ports A and B, to which the joysticks and cassette are attached: 0=Input, 1=Output. Register 7 must always contain 10xxxxxx or possible damage could result to the PSG, there are active devices connected to its I/O pins. The BASIC "SOUND" statement will force these bits to the correct value for Register 7 but there is no protection at the machine code level.

3. PROGRAMMABLE SOUND GENERATOR

and two trigger buttons on a joystick: 0=Pressed, 1=Not pressed. Alternatively up to six Paddles may be connected instead of one joystick. Although most MSX machines have two 9 pin joystick connectors only one can be read at a time. The one to be selected for reading is determined by the Joystick Select bit in PSG Register 15.

The Keyboard Mode bit is unused on UK machines. On Japanese machines it is tied to a jumper link to determine the keyboard's character set.

The Cassette Input is used to read the signal from the cassette EAR output. This is passed through a comparator to clean the edges and to convert to digital levels but is otherwise unprocessed.

Register 15

Figure 33

This register is used to output to PSG Port B. The four least significant bits are connected via TTL open-collector buffers to pins 6 and 7 of each joystick connector. They are normally set to a 1, when a paddle or joystick is connected, so that the pins can function as inputs. When a touchpad is connected they are used as handshaking outputs.

The two Pulse bits are used to generate a short positive-going pulse to any paddles attached to joystick connectors 1 or 2. Each paddle contains a monostable timer with a variable resistor controlling its pulse length. Once the timer is triggered the position of the variable resistor can be determined by counting until the monostable times out.

The Joystick Select bit determines which joystick connector is connected to PSG Port A for input: 0=Connector 1, 1=Connector 2.

The Kana LED output is unused on UK machines. On Japanese machines it is used to drive a keyboard mode indicator.

4. ROM BIOS

The design of the MSX ROM is of importance if machine code programs are to be developed efficiently and Operate reliably. Almost every program, including the BASIC Interpreter itself, will require a certain set of primitive functions to operate. These include screen and printer drivers, a keyboard decoder and other hardware related functions. By separating these routines from the BASIC Interpreter they can be made available to any application program. The section of ROM from 0000H to 268BH is largely devoted to such routines and is called the ROM BIOS (Basic Input Output System).

This chapter gives a functional description of every recognizably separate routine in the ROM BIOS. Special attention is given to the "standard" routines. These are documented by Microsoft and guaranteed to remain consistent through possible hardware and software changes. The first few hundred bytes of the ROM consists of Z80 JP instructions which provide fixed position entry points to these routines. For maximum compatibility with future software an application program should restrict its dependence on the ROM to these locations only. The description of the ROM begins with this list of entry points to the standard routines. A brief comment is placed with each entry point, the full description is given with the routine itself.

Data Areas

It is expected that most users will wish to disassemble the ROM to some extent (the full listing runs to nearly four hundred pages). In order to ease this process the data areas, which do not contain executable Z80 code, are shown below:

0004H-0007H	185DH-1863H	4B3AH-4B4CH	73E4H-73E4H
002BH-002FH	1B97H-1BAAH	4C2FH-4C3FH	752EH-7585H
0508H-050DH	1BBFH-23BEH	555AH-5569H	7754H-7757H

Note that these data areas are for the UK ROM, there are slight differences in the Japanese ROM relating to the keyboard decoder and the video character set. Disparities between the ROMs are restricted to these regions with the bulk of the code being identical in both cases.

4. ROM BIOS

Terminology

Reference is frequently made in this chapter to the standard routines and to Workspace Area variables. Whenever this is done the Microsoft-recommended name is used in upper case letters, for example "the FILVRM standard routine" and "SCRMOD is set". Subroutines which are not named are referred to by a parenthesized address, "the screen is cleared (0777H)" for example. When reference is made to the Z80 status flags assembly language conventions are used, for example "Flag C" would mean that the carry flag is set while "Flag NZ" means that the zero flag is reset. The terms "EI" and "DI" mean enabled interrupts and disabled interrupts respectively.

ADDR.	NAME	TO	FUNCTION
0000H	CHKRAM	02D7H	Power-up, check RAM
0004H		Two bytes, address of ROM character set
0006H		One byte, VDP Data Port number
0007H		One byte, VDP Data Port number
0008H	SYNCHR	2683H	Check BASIC program character
000BH		NOP
000CH	RDSLTL	01B6H	Read RAM in any slot
000FH		NOP
0010H	CHRGTR	2686H	Get next BASIC program character
0013H		NOP
0014H	WRSLTL	01D1H	Write to RAM in any slot
0017H		NOP
0018H	OUTDO	1B45H	Output to current device
001BH		NOP
001CH	CALSLT	0217H	Call routine in any slot
001FH		NOP
0020H	DCOMPR	146AH	Compare register pairs HL and DE
0023H		NOP
0024H	ENASLT	025EH	Enable any slot permanently
0027H		NOP
0028H	GETYPR	2689H	Get BASIC operand type
002BH		Five bytes Version Number
0030H	CALLF	0205H	Call routine in any slot
0033H		Five NOPs
0038H	KEYINT	0C3CH	Interrupt handler, keyboard scan
003BH	INITIO	049DH	Initialize I/O devices
003EH	INIFNK	139DH	Initialize function key strings
0041H	DISSCR	0577H	Disable screen
0044H	ENASCR	0570H	Enable screen
0047H	WRTVDP	057FH	Write to any VDP register
004AH	RDVRM	07D7H	Read byte from VRAM
004DH	WRTVRM	07CDH	Write byte to VRAM
0050H	SETRD	07ECH	Set up VDP for read
0053H	SETWRT	07DFH	Set up VDP for write
0056H	FILVRM	0815H	Fill block of VRAM with data byte
0059H	LDIRMV	070FH	Copy block to memory from VRAM
005CH	LDIRVM	0744H	Copy block to VRAM, from memory
005FH	CHGMOD	084FH	Change VDP mode

015CH NOPS to 01B5H for expansion

Address... 01B6H
Name..... RDSL
Entry..... A=Slot ID, HL=Address
Exit..... A=Byte read
Modifies.. AF, BC, DE, DI

Standard routine to read a single byte from memory in any slot. The Slot Identifier is composed of a Primary Slot number a Secondary Slot number and a flag:

Figure 34: Slot ID

The flag is normally 0 but must be 1 if a Secondary Slot number is included in the Slot ID. The memory address and Slot ID are first processed (027EH) to yield a set of bit masks to apply to the relevant slot register. If a Secondary Slot number is

4. ROM BIOS

specified then the Secondary Slot Register is first modified to select the relevant page from that Secondary Slot (02A3H). The Primary Slot is then switched in to the Z80 address space, the byte read and the Primary Slot restored to its original setting via the RDPRIM routine in the Workspace Area. Finally, if a Secondary Slot number is included in the Slot ID, the original Secondary Slot Register setting is restored (01ECH).

Note that, unless it is the slot containing the Workspace Area, any attempt to access page 3 (C000H to FFFFH) will cause the system to crash as RDPRIM will switch itself out. Note also that interrupts are left disabled by all the memory switching routines.

```
Address... 01D1H
Name..... WRSLT
Entry..... A=Slot ID, HL=Address, E=Byte to write
Exit..... None
Modifies.. AF, BC, D, DI
```

Standard routine to write a single byte to memory in any slot. Its operation is fundamentally the same as that of the RDSLTL standard routine except that the Workspace Area routine WRPRIM is used rather than RDPRIM.

```
Address... 01FFH
Name..... CALBAS
Entry..... IX=Address
Exit..... None
Modifies.. AF', BC', DE', HL', IY, DI
```

Standard routine to call an address in the BASIC Interpreter from any slot. Usually this will be from a machine code program running in an extension ROM in page 1 (4000H to 7FFFH). The high byte of register pair IY is loaded with the MSX ROM Slot ID (00H) and control transfers to the CALSLTL standard routine.

```
Address... 0205H
Name..... CALLF
Entry..... None
Exit..... None
Modifies.. AF', BC', DE', HL', IX, IY, DI
```

Standard routine to call an address in any slot. The Slot ID and address are supplied as inline parameters rather than in registers to fit inside a hook (Chapter 6), for example:

```
RST 30H
DEFB Slot ID
DEFW Address
RET
```

The Slot ID is first collected and placed in the high byte of register pair IY. The address is then placed in register pair

4. ROM BIOS

IX and control drops into the CALSLT standard routine.

```
Address... 0217H
Name..... CALSLT
Entry..... IY(High byte)=Slot ID, IX=Address
Exit..... None
Modifies.. AF', BC', DE', HL', DI
```

Standard routine to call an address in any slot. Its operation is fundamentally the same as that of the RDSLT standard routine except that the Workspace Area routine CLPRIM is used rather than RDPRIM. Note that CALBAS and CALLF are just specialized entry points to this standard routine which offer a reduction in the amount of code required.

```
Address... 025EH
Name..... ENASLT
Entry..... A=Slot ID, HL=Address
Exit..... None
Modifies.. AF, BC, DE, DI
```

Standard routine to switch in a page permanently from any slot. Unlike the RDSLT, WRSLT and CALSLT standard routines the Primary Slot switching is performed directly and not by a Workspace Area routine. Consequently addresses in page 0 (0000H to 3FFFH) will cause an immediate system crash.

```
Address... 027EH
```

This routine is used by the memory switching standard routines to turn an address, in register pair HL, and a Slot ID, in register A, into a set of bit masks. As an example a Slot ID of FxxxSSPP and an address in Page 1 (4000H to 7FFFH) would return the following:

```
Register B=00 00 PP 00 (OR mask)
Register C=11 11 00 11 (AND mask)
Register D=PP PP PP PP (Replicated)
Register E=00 00 11 00 (Page mask)
```

Registers B and C are derived from the Primary Slot number and the page mask. They are later used to mix the new Primary Slot number into the existing contents of the Primary Slot Register. Register D contains the Primary Slot number replicated four times and register E the page mask. This is produced by examining the two most significant bits of the address, to determine the page number, and then shifting the mask along to the relevant position. These registers are later used during Secondary Slot switching.

As the routine terminates bit 7 of the Slot ID is tested, to determine whether a Secondary Slot has been specified, and Flag M returned if this is so.

4. ROM BIOS

Address... 02A3H

This routine is used by the memory switching standard routines to modify a Secondary Slot Register. The Slot ID is supplied in register A while registers D and E contain the bit masks shown in the previous routine.

Bits 6 and 7 of register D are first copied into the Primary Slot register. This switches in page 3 from the Primary Slot specified by the Slot ID and makes the required Secondary Slot Register available. This is then read from memory location FFFFH and the page mask, inverted, used to clear the required two bits. The Secondary Slot number is shifted to the relevant position and mixed in. Finally the new setting is placed in the Secondary Slot Register and the Primary Slot Register restored to its original setting.

Address... 02D7H
Name..... CHKRAM
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, SP

Standard routine to perform memory initialization at power-up. It non-destructively tests for RAM in pages 2 and 3 in all sixteen possible slots then sets the Primary and Secondary Slot registers to switch in the largest area found. The entire Workspace Area (F380H to FFC9H) is zeroed and EXPTBL and SLTTBL filled in to map any expansion interfaces in existence. Interrupt Mode 1 is set and control transfers to the remainder of the power-up initialization routine (7C76H).

Address... 03FBH
Name..... ISCNTC
Entry..... None
Exit..... None
Modifies.. AF, EI

Standard routine to check whether the CTRL-STOP or STOP keys have been pressed. It is used by the BASIC Interpreter at the end of each statement to check for program termination. BASROM is first examined to see if it contains a non-zero value, if so the routine terminates immediately. This is to prevent users breaking into any extension ROM containing a BASIC program.

INTFLG is then checked to determine whether the interrupt handler has placed the CTRL-STOP or STOP key codes (03H or 04H) there. If STOP has been detected then the cursor is turned on (09DAH) and INTFLG continually checked until one of the two key codes reappears. The cursor is then turned off (0A27H) and, if the key is STOP, the routine terminates.

If CTRL-STOP has been detected then the keyboard buffer is first cleared via the KILBUF standard routine and TRPTBL is

4. ROM BIOS

checked to see whether an "ON STOP GOSUB" statement is active. If so the relevant entry in TRPTBL is updated (0EF1H) and the routine terminates as the event will be handled by the Interpreter Runloop. Otherwise the ENASLT standard routine is used to switch in page 1 from the MSX ROM, in case an extension ROM is using the routine, and control transfers to the "STOP" statement handler (63E6H).

Address... 0468H
Name..... KILBUF
Entry..... None
Exit..... None
Modifies.. HL

Standard Routine to clear the forty character type-ahead keyboard buffer KEYBUF. There are two pointers into this buffer, PUTPNT where the interrupt handler places characters, and GETPNT where application programs fetch them from. As the number of characters in the buffer is indicated by the difference between these two pointers KEYBUF is emptied simply by making them both equal.

Address... 046FH
Name..... BREAKX
Entry..... None
Exit..... Flag C if CTRL-STOP key pressed
Modifies.. AF

Standard routine which directly tests rows 6 and 7 of the keyboard to determine whether the CTRL and STOP keys are both pressed. If they are then KEYBUF is cleared and row 7 of OLDKEY modified to prevent the interrupt handler picking the keys up as well. This routine may often be more suitable for use by an application program, in preference to ISCNTC, as it will work when interrupts are disabled, during cassette I/O for example, and does not exit to the Interpreter.

Address... 049DH
Name..... INITIO
Entry..... None
Exit..... None
Modifies.. AF, E, EI

Standard routine to initialize the PSG and the Centronics Status Port. PSG Register 7 is first set to 80H making PSG Port B=Output and PSG Port A=Input. PSG Register 15 is set to CFH to initialize the Joystick connector control hardware. PSG Register 14 is then read and the Keyboard Mode bit placed in KANAMD, this has no relevance for UK machines.

Finally a value of FFH is output to the Centronics Status Port (I/O port 90H) to set the STROBE signal high. Control then drops into the GICINI standard routine to complete initialization.

4. ROM BIOS

Address... 04BDH
Name..... GICINI
Entry..... None
Exit..... None
Modifies.. EI

Standard routine to initialize the PSG and the Workspace Area variables associated with the "PLAY" statement. QUETAB, VCBA, VCBB and VCBC are first initialized with the values shown in Chapter 6. PSG Registers 8, 9 and 10 are then set to zero amplitude and PSG Register 7 to B8H. This enables the Tone Generator and disables the Noise Generator on each channel.

Address... 0508H

This six byte table contains the "PLAY" statement parameters initially placed in VCBA, VCBB and VCBC by the GICINI standard routine: Octave=4, Length=4, Tempo=120, Volume=88H, Envelope=00FFH.

Address... 050EH
Name..... INITXT
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to initialize the VDP to 40x24 Text Mode. The screen is temporarily disabled via the DISSCR standard routine and SCRMOD and OLDSCR set to 00H. The parameters required by the CHPUT standard routine are set up by copying LINI.40 to LINLEN, TXTNAM to NAMBAS and TXTCGP to CGPBAS. The VDP colours are then set by the CHGCLR standard routine and the screen is cleared (077EH). The current character set is copied into the VRAM Character Pattern Table (071EH). Finally the VDP mode and base addresses are set via the SETTXT standard routine and the screen is enabled.

Address... 0538H
Name..... INIT32
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to initialize the VDP to 32x24 Text Mode. The screen is temporarily disabled via the DISSCR standard routine and SCRMOD and OLDSCR set to 01H. The parameters required by the CHPUT standard routine are set up by copying LINL32 to LINLEN, T32NAM to NAMBAS, T32CGP to CGPBAS, T32PAT to PATBAS and T32ATR to ATRBAS. The VDP colours are then set via the CHGCLR standard routine and the screen is cleared (077EH). The current character set is copied into the VRAM Character Pattern Table (071EH) and all sprites cleared (06BBH). Finally the VDP mode and base addresses are set via the SETT32 standard routine and the screen is enabled.

4. ROM BIOS

Address... 0570H
Name..... ENASCR
Entry..... None
Exit..... None
Modifies.. AF, BC, EI

Standard routine to enable the screen. This simply involves setting bit 6 of VDP Mode Register 1.

Address... 0577H
Name..... DISSCR
Entry..... None
Exit..... None
Modifies.. AF, BC, EI

Standard routine to disable the screen. This simply involves resetting bit 6 of VDP Mode Register 1.

Address... 057FH
Name..... WRTVDP
Entry..... B=Data byte, C=VDP Mode Register number
Exit..... None
Modifies.. AF, B, EI

Standard routine to write a data byte to any VDP Mode Register. The register selection byte is first written to the VDP Command Port, followed by the data byte. This is then copied to the relevant register image, RGOSAV to RG7SAV, in the Workspace Area

Address... 0594H
Name..... SETTXT
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to partially set the VDP to 40x24 Text Mode. The mode bits M1, M2 and M3 are first set in VDP Mode Registers 0 and 1. The five VRAM table base addresses, beginning with TXTNAM, are then copied from the Workspace Area into VDP Mode Registers 2, 3, 4, 5 and 6 (0677H).

Address... 05B4H
Name..... SETT32
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to partially set the VDP to 32x24 Text Mode. The mode bits M1, M2 and M3 are first set in VDP Mode Registers 0 and 1. The five VRAM table base addresses, beginning with T32NAM, are then copied from the Workspace Area into VDP Mode Registers 2, 3, 4, 5 and 6 (0677H).

4. ROM BIOS

Address... 05D2H
Name..... INIGRP
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to initialize the VDP to Graphics Mode. The screen is temporarily disabled via the DISSCR standard routine and SCRMOD set to 02H. The parameters required by the GRPPRT standard routine are set up by copying GRPPAT to PATBAS and GRPATR to ATRBAS. The character code driver pattern is then copied into the VDP Name Table, the screen cleared (07A1H) and all sprites cleared (06BBH). Finally the VDP mode and base addresses are set via the SETGRP standard routine and the screen is enabled.

Address... 0602H
Name..... SETGRP
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to partially set the VDP to Graphics Mode. The mode bits M1, M2 and M3 are first set in VDP Mode Registers 0 and 1. The five VRAM table base addresses, beginning with GRPNAM, are then copied from the Workspace Area into VDP Mode Registers 2, 3, 4, 5 and 6 (0677H).

Address... 061FH
Name..... INIMLT
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to initialize the VDP to Multicolour Mode. The screen is temporarily disabled via the DISSCR standard routine and SCRMOD set to 03H. The parameters required by the GRPPRT standard routine are set up by copying MLTPAT to PATBAS and MLTATR to ATRBAS. The character code driver pattern is then copied into the VDP Name Table, the screen cleared (07B9H) and all sprites cleared (06BBH). Finally the VDP mode and base addresses are set via the SETMLT standard routine and the screen is enabled.

Address... 0659H
Name..... SETMLT
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to partially set the VDP to Multicolour Mode. The mode bits M1, M2 and M3 are first set in VDP Mode Registers 0 and 1. The five VRAM table base addresses, beginning with MLTNAM, are then copied from the Workspace Area

4. ROM BIOS

to VDP Mode Registers 2, 3, 4, 5 and 6.

Address... 0677H

This routine is used by the SETTXT, SETT32, SETGRP and SETMLT standard routines to copy a block of five table base addresses from the Workspace Area into VDP Mode Registers 2, 3, 4, 5 and 6. On entry register pair HL points to the relevant group of addresses. Each base address is collected in turn shifted the required number of places and then written to the relevant Mode Register via the WRTVDP standard routine.

Address... 06A8H
Name..... CLRSPR
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to clear all sprites. The entire 2 KB Sprite Pattern Table is first filled with zeros via the FILVRM standard routine. The vertical coordinate of each of the thirty-two sprite attribute blocks is then set to -47 (D1H) to place the sprite above the top of the screen, the horizontal coordinate is left unchanged.

The pattern numbers in the Sprite Attribute Table are initialized with the series 0, 1, 2, 3, 4,... 31 for 8x8 sprites or the series 0, 4, 8, 12, 16,... 124 for 16x16 sprites. The series to be generated is determined by the Size bit in VDP Mode Register 1. Finally the colour byte of each sprite attribute block is filled in with the colour code contained in FORCLR, this is initially white.

Note that the Size and Mag bits in VDP Mode Register 1 are not affected by this routine. Note also that the INIT32, INIGRP and INIMLT standard routines use this routine with an entry point at 06BBH, leaving the Sprite Pattern Table undisturbed.

Address... 06E4H
Name..... CALPAT
Entry..... A=Sprite pattern number
Exit..... HL=Sprite pattern address
Modifies.. AF, DE, HL

Standard routine to calculate the address of a sprite pattern. The pattern number is first multiplied by eight then, if 16x16 sprites are selected, multiplied by a further factor of four. This is then added to the Sprite Pattern Table base address, taken from PATBAS, to produce the final address.

This numbering system is in line with the BASIC Interpreter's usage of pattern numbers rather than the VDP's when 16x16 sprites are selected. As an example while the Interpreter calls the second pattern number one, it is actually

4. ROM BIOS

VDP pattern number four. This usage means that the maximum pattern number this routine should allow, when 16x16 sprites are selected, is sixty-three. There is no actual check on this limit so large pattern numbers will produce addresses greater than 3FFFH. Such addresses, when passed to the other VDP routines, will wrap around past zero and corrupt the Character Pattern Table in VRAM.

Address... 06F9H
Name..... CALATR
Entry..... A=Sprite number
Exit..... HL=Sprite attribute address
Modifies.. AF, DE, HL

Standard routine to calculate the address of a sprite attribute block. The sprite number, from zero to thirty-one, is multiplied by four and added to the Sprite Attribute Table base address taken from ATRBAS.

Address... 0704H
Name..... GSPSIZ
Entry..... None
Exit..... A=Bytes in sprite pattern (8 or 32)
Modifies.. AF

Standard routine to return the number of bytes occupied by each sprite pattern in the Sprite Pattern Table. The result is determined simply by examining the Size bit in VDP Mode Register 1.

Address... 070FH
Name..... LDIRMV
Entry..... BC=Length, DE=RAM address, HL=VRAM address
Exit..... None
Modifies.. AF, BC, DE, EI

Standard routine to copy a block into main memory from the VDP VRAM. The VRAM starting address is set via the SETRD standard routine and then sequential bytes read from the VDP Data Port and placed in main memory.

Address... 071EH

This routine is used to copy a 2 KB character set into the VDP Character Pattern Table in any mode. The base address of the Character Pattern Table in VRAM is taken from CGPBAS. The starting address of the character set is taken from CGPNT. The RDSLT standard routine is used to read the character data so this may be situated in an extension ROM.

At power-up CGPNT is initialized with the address contained at ROM location 0004H, which is 1BBFH. CGPNT is easily altered to produce some interesting results, POKE &HF920,&HC7:SCREEN 0 provides a thoroughly confusing example.

4. ROM BIOS

Address... 0744H
Name..... LDIRVM
Entry..... BC=Length, DE=VRAM address, HL=RAM address
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to copy a block to VRAM from main memory. The VRAM starting address is set via the SETWRT standard routine and then sequential bytes taken from main memory and written to the VDP Data Port.

Address... 0777H

This routine will clear the screen in any VDP mode. In 40x24 Text Mode and 32x24 Text Mode the Name Table, whose base address is taken from NAMBAS, is first filled with ASCII spaces. The cursor is then set to the home position (0A7FH) and LINTTB, the line termination table, re-initialized. Finally the function key display is restored, if it is enabled, via the FNKSB standard routine.

In Graphics Mode the border colour is first set via VDP Mode Register 7 (0832H). The Colour Table is then filled with the background colour code, taken from BAKCLR, for both 0 and 1 pixels. Finally the Character Pattern Table is filled with zeroes.

In Multicolour Mode the border colour is first set via VDP Mode Register 7 (0832H). The Character Pattern Table is then filled with the background colour taken from BAKCLR.

Address... 07CDH
Name..... WRTVRM
Entry..... A=Data byte, HL=VRAM address
Exit..... None
Modifies.. EI

Standard routine to write a single byte to the VDP VRAM. The VRAM address is first set up via the SETWRT standard routine and then the data byte written to the VDP Data Port. Note that the two seemingly spurious EX(SP),HL instructions in this routine, and several others, are required to meet the VDP's timing constraints.

Address... 07D7H
Name..... RDVRM
Entry..... HL=VRAM address
Exit..... A=Byte read
Modifies.. AF, EI

Standard routine to read a single byte from the VDP VRAM. The VRAM address is first set up via the SETRD standard routine and then the byte read from the VDP Data Port.

4. ROM BIOS

Address... 07DFH
Name..... SETWRT
Entry..... HL=VRAM address
Exit..... None
Modifies.. AF, EI

Standard routine to set up the VDP for subsequent writes to VRAM via the Data Port. The address contained in register pair HL is written to the VDP Command Port LSB first, MSB second as shown in Figure 7. Addresses greater than 3FFFH will wrap around past zero as the two most significant bits of the address are ignored.

Address... 07ECH
Name..... SETRD
Entry..... HL=VRAM address
Exit..... None
Modifies.. AF, EI

Standard routine to set up the VDP for subsequent reads from VRAM via the Data Port. The address contained in register pair HL is written to the VDP Command Port LSB first, MSB second as shown in Figure 7. Addresses greater than 3FFFH will wrap around past zero as the two most significant bits of the address are ignored.

Address... 07F7H
Name..... CHGCLR
Entry..... None
Exit..... None
Modifies.. AF, BC, HL, EI

Standard routine to set the VDP colours. SCRMOD is first examined to determine the appropriate course of action. In 40x24 Text Mode the contents of BAKCLR and FORCLR are written to VDP Mode Register 7 to set the colour of the 0 and 1 pixels, these are initially blue and white. Note that in this mode there is no way of specifying the border colour, this will be the same as the 0 pixel colour. In 32x24 Text Mode, Graphics Mode or Multicolour Mode the contents of BDRCLR are written to VDP Mode Register 7 to set the colour of the border, this is initially blue. Also in 32x24 Text Mode the contents of BAKCLR and FORCLR are copied to the whole of the Colour Table to determine the 0 and 1 pixel colours.

Address... 0815H
Name..... FILVRM
Entry..... A=Data byte, BC=Length, HL=VRAM address
Exit..... None
Modifies.. AF, BC, EI

Standard routine to fill a block of the VDP VRAM with a single data byte. The VRAM starting address, contained in register pair HL, is first set up via the SETWRT standard

4. ROM BIOS

routine. The data byte is then repeatedly written to the VDP Data Port to fill successive VRAM locations.

```
Address... 083BH
Name..... TOTEXT
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, HL, EI
```

Standard routine to return the VDP to either 40x24 Text Mode or 32x24 Text Mode if it is currently in Graphics Mode or Multicolour Mode. It is used by the BASIC Interpreter Mainloop and by the "INPUT" statement handler. Whenever the INITXT or INIT32 standard routines are used the mode byte, 00H or 01H, is copied into OLDSCR. If the mode is subsequently changed to Graphics Mode or Multicolour Mode, and then has to be returned to one of the two text modes for keyboard input, this routine ensures that it returns to the same one.

SCRMOD is first examined and, if the screen is already in either text mode, the routine simply terminates with no action. Otherwise the previous text mode is taken from OLDSCR and passed to the CHGMOD standard routine.

```
Address... 0848H
Name..... CLS
Entry..... Flag Z
Exit..... None
Modifies.. AF, BC, DE, EI
```

Standard routine to clear the screen in any mode, it does nothing but call the routine at 0777H. This is actually the "CLS" statement handler and, because this indicates that there is illegal text after the statement, it will simply return if entered with Flag NZ.

```
Address... 084FH
Name..... CHGMOD
Entry..... A=Screen mode required (0, 1, 2, 3)
Exit..... None
Modifies.. AF, BC, DE, HL, EI
```

Standard routine to set a new screen mode. Register A, containing the required screen mode, is tested and control transferred to INITXT, INIT32, INIGRP or INIMLT.

```
Address... 085DH
Name..... LPTOUT
Entry..... A=Character to print
Exit..... Flag C if CTRL-STOP termination
Modifies.. AF
```

Standard routine to output a character to the line printer via the Centronics Port. The printer status is continually

4. ROM BIOS

tested, via the LPTSTT standard routine, until the printer becomes free. The character is then written to the Centronics Data Port (I/O port 91H) and the STROBE signal of the Centronics Status Port (I/O port 90H) briefly pulsed low. Note that the BREAKX standard routine is used to test for the CTRL-STOP key if the printer is busy. If CTRL-STOP is detected a CR code is written to the Centronics Data Port, to flush the printer's line buffer, and the routine terminates with Flag C.

Address... 0884H
Name..... LPTSTT
Entry..... None
Exit..... A=0 and Flag Z if printer busy
Modifies.. AF

Standard routine to test the Centronics Status Port BUSY signal. This just involves reading I/O port 90H and examining the state of bit 1: 0=Ready, 1=Busy.

Address... 088EH
Name..... POSIT
Entry..... H=Column, L=Row
Exit..... None
Modifies.. AF, EI

Standard routine to set the cursor coordinates. The row and column coordinates are sent to the OUTDO standard routine as the parameters in an ESC,"Y",Row+1FH, Column+1FH sequence. Note that the BIOS home position has coordinates of 1,1 rather than the 0,0 used by the BASIC Interpreter.

Address... 089DH
Name..... CNVCHR
Entry..... A=Character
Exit..... Flag Z,NC=Header; Flag NZ,C=Graphic; Flag Z,C=Normal
Modifies.. AF

Standard routine to test for, and convert if necessary, characters with graphic headers. Characters less than 20H are normally interpreted by the output device drivers as control characters. A character code in this range can be treated as a displayable character by preceding it with a graphic header control code (01H) and adding 40H to its value. For example to directly display character code 0DH, rather than have it interpreted as a carriage return, it is necessary to output the two bytes 01H,4DH. This routine is used by the output device drivers, such as the CHPUT standard routine, to check for such sequences.

If the character is a graphic header GRPHED is set to 01H and the routine terminates, otherwise GRPHED is zeroed. If the character is outside the range 40H to 5FH it is left unchanged. If it is inside this range, and GRPHED contains 01H indicating a previous graphic header, it is converted by subtracting 40H.

4. ROM BIOS

Address... 08BCH
Name..... CHPUT
Entry..... A=Character
Exit..... None
Modifies.. EI

Standard routine to output a character to the screen in 40x24 Text Mode or 32x24 Text Mode. SCRMOD is first checked and, if the VDP is in either Graphics Mode or Multicolour Mode, the routine terminates with no action. Otherwise the cursor is removed (0A2EH), the character decoded (08DFH) and then the cursor replaced (09E1H). Finally the cursor column position is placed in TTYPOS, for use by the "PRINT" statement, and the routine terminates.

Address... 08DFH

This routine is used by the CHPUT standard routine to decode a character and take the appropriate action. The CNVCHR standard routine is first used to check for a graphic character, if the character is a header code (01H) then the routine terminates with no action. If the character is a converted graphic one then the control code decoding section is skipped. Otherwise ESCCNT is checked to see if a previous ESC character (1BH) has been received, if so control transfers to the ESC sequence processor (098FH). Otherwise the character is checked to see if it is smaller than 20H, if so control transfers to the control code processor (0914H). The character is then checked to see if it is DEL (7FH), if so control transfers to the delete routine (0AE3H).

Assuming the character is displayable the cursor coordinates are taken from CSRY and CSRX and placed in register pair HL, H=Column, L=Row. These are then converted to a physical address in the VDP Name Table and the character placed there (0BE6H). The cursor column position is then incremented (0A44H) and, assuming the rightmost column has not been exceeded, the routine terminates. Otherwise the row's entry in LINTTB, the line termination table, is zeroed to indicate an extended logical line, the column number is set to 01H and a LF is performed.

Address... 0908H

This routine performs the LF operation for the CHPUT standard routine control code processor. The cursor row is incremented (0A61H) and, assuming the lowest row has not been exceeded, the routine terminates. Otherwise the screen is scrolled upwards and the lowest row erased (0A88H).

Address... 0914H

This is the control code processor for the CHPUT standard routine. The table at 092FH is searched for a match with the

4. ROM BIOS

code and control transferred to the associated address.

Address... 092FH

This table contains the control codes, each with an associated address, recognized by the CHPUT standard routine:

CODE	TO	FUNCTION
07H	1113H	BELL, go beep
08H	0A4CH	BS, cursor left
09H	0A71H	TAB, cursor to next tab position
0AH	0908H	LF, cursor down a row
0BH	0A7FH	HOME, cursor to home
0CH	077EH	FORMFEED, clear screen and home
0DH	0A81H	CR, cursor to leftmost column
1BH	0989H	ESC, enter escape sequence
1CH	0A5BH	RIGHT, cursor right
1DH	0A4CH	LEFT, cursor left
1EH	0A57H	UP, cursor up
1FH	0A61H	DOWN, cursor down.

Address... 0953H

This table contains the ESC control codes, each with an associated address, recognized by the CHPUT standard routine:

CODE	TO	FUNCTION
6AH	077EH	ESC,"j", clear screen and home
45H	077EH	ESC,"E", clear screen and home
4BH	0AEEH	ESC,"K", clear to end of line
4AH	0B05H	ESC,"J", clear to end of screen
6CH	0AECB	ESC,"l", clear line
4CH	0AB4H	ESC,"L", insert line
4DH	0A85H	ESC,"M", delete line
59H	0986H	ESC,"Y", set cursor coordinates
41H	0A57H	ESC,"A", cursor up
42H	0A61H	ESC,"B", cursor down
43H	0A44H	ESC,"C", cursor right
44H	0A55H	ESC,"D", cursor left
48H	0A7FH	ESC,"H", cursor home
78H	0980H	ESC,"x", change cursor
79H	0983H	ESC,"y", change cursor

Address... 0980H

This routine performs the ESC,"x" operation for the CHPUT standard routine control code processor. ESCCNT is set to 01H to indicate that the next character received is a parameter.

Address... 0983H

This routine performs the ESC,"y" operation for the CHPUT

4. ROM BIOS

standard routine control code decoder. ESCCNT is set to 02H to indicate that the next character received is a parameter.

Address... 0986H

This routine performs the ESC",Y" operation for the CHPUT standard routine control code processor. ESCCNT is set to 04H to indicate that the next character received is a parameter.

Address... 0989H

This routine performs the ESC operation for the CHPUT standard routine control code processor. ESCCNT is set to FFH to indicate that the next character received is the second control character.

Address... 098FH

This is the CHPUT standard routine ESC sequence processor. If ESCCNT contains FFH then the character is the second control character and control transfers to the control code processor (0919H) to search the ESC code table at 0953H.

If ESCCNT contains 01H then the character is the single parameter of the ESC,"x" sequence. If the parameter is "4" (34H) then CSTYLE is set to 00H resulting in a block cursor. If the parameter is "5" (35H) then CSRSW is set to 00H making the cursor normally disabled.

If ESCCNT contains 02H then the character is the single parameter in the ESC,"y" sequence. If the parameter is "4" (34H) then CSTYLE is set to 01H resulting in an underline cursor. If the parameter is "5" (35H) then CSRSW is set to 01H making the cursor normally enabled.

If ESCCNT contains 04H then the character is the first parameter of the ESC,"Y" sequence and is the row coordinate. The parameter has 1FH subtracted and is placed in CSRY, ESCCNT is then decremented to 03H.

If ESCCNT contains 03H then the character is the second parameter of the ESC,"Y" sequence and is the column coordinate. The parameter has 1FH subtracted and is placed in CSRX.

Address... 09DAH

This routine is used, by the CHGET standard routine for example, to display the cursor character when it is normally disabled. If CSRSW is non-zero the routine simply terminates with no action, otherwise the cursor is displayed (09E6H).

Address... 09E1H

This routine is used, by the CHPUT standard routine for

4. ROM BIOS

example, to display the cursor character when it is normally enabled. If CSRSW is zero the routine simply terminates with no action. SCRMOD is checked and, if the screen is in Graphics Mode or Multicolour Mode, the routine terminates with no action. Otherwise the cursor coordinates are converted to a physical address in the VDP Name Table and the character read from that location (0BD8H) and saved in CURSAV.

The character's eight byte pixel pattern is read from the VDP Character Pattern Table into the LINWRK buffer (0BA5H). The pixel pattern is then inverted, all eight bytes if CSTYLE indicates a block cursor, only the bottom three if CSTYLE indicates an underline cursor. The pixel pattern is copied back to the position for character code 255 in the VDP Character Pattern Table (0BBEH). The character code 255 is then placed at the current cursor location in the VDP Name Table (0BE6H) and the routine terminates.

This method of generating the cursor character, by using character code 255, can produce curious effects under certain conditions. These can be demonstrated by executing the BASIC statement FOR N=1 TO 100: PRINT CHR\$(255);:NEXT and then pressing the cursor up key.

Address... 0A27H

This routine is used, by the CHGET standard routine for example, to remove the cursor character when it is normally disabled. If CSRSW is non-zero the routine simply terminates with no action, otherwise the cursor is removed (0A33H).

Address... 0A2EH

This routine is used, by the CHPUT standard routine for example, to remove the cursor character when it is normally enabled. If CSRSW is zero the routine simply terminates with no action. SCRMOD is checked and, if the screen is in Graphics Mode or Multicolour Mode, the routine terminates with no action. Otherwise the cursor coordinates are converted to a physical address in the VDP Name Table and the character held in CURSAV written to that location (0BE6H).

Address... 0A44H

This routine performs the ESC,"C" operation for the CHPUT standard routine control code processor. If the cursor column coordinate is already at the rightmost column, determined by LINLEN, then the routine terminates with no action. Otherwise the column coordinate is incremented and CSRX updated. .

Address... 0A4CH

This routine performs the BS/LEFT operation for the CHPUT standard routine control code processor. The cursor column

4. ROM BIOS

coordinate is decremented and CSRX updated. If the column coordinate has moved beyond the leftmost position it is set to the rightmost position, from LINLEN, and an UP operation performed.

Address... 0A55H

This routine performs the ESC,"D" operation for the CHPUT standard routine control code processor. If the cursor column coordinate is already at the leftmost position then the routine terminates with no action. Otherwise the column coordinate is decremented and CSRX updated.

Address... 0A57H

This routine performs the ESC,"A" (UP) operation for the CHPUT standard routine control code processor. If the cursor row coordinate is already at the topmost position the routine terminates with no action. Otherwise the row coordinate is decremented and CSRY updated.

Address... 0A5BH

This routine performs the RIGHT operation for the CHPUT standard routine control code processor. The cursor column coordinate is incremented and CSRX updated. If the column coordinate has moved beyond the rightmost position, determined by LINLEN, it is set to the leftmost position (01H) and a DOWN operation performed.

Address... 0A61H

This routine performs the ESC,"B" (DOWN) operation for the CHPUT standard routine control code processor. If the cursor row coordinate is already at the lowest position, determined by CRTCNT and CNSDFG (0C32H), then the routine terminates with no action. Otherwise the row coordinate is incremented and CSRY updated.

Address... 0A71H

This routine performs the TAB operation for the CHPUT standard routine control code processor. ASCII spaces are output (08DFH) until CSRX is a multiple of eight plus one (BIOS columns 1, 9, 17, 25, 33).

Address... 0A7FH

This routine performs the ESC,"H" (HOME) operation for the CHPUT standard routine control code processor, CSRX and CSRY are simply set to 1,1. The ROM BIOS cursor coordinate system, while functionally identical to that used by the BASIC Interpreter, numbers the screen rows from 1 to 24 and the columns from 1 to 32/40.

4. ROM BIOS

Address... 0A81H

This routine performs the CR operation for the CHPUT standard routine control code processor, CSRX is simply set to 01H .

Address... 0A85H

This routine performs the ESC,"M" function for the CHPUT standard routine control code processor. A CR operation is first performed to set the cursor column coordinate to the leftmost position. The number of rows from the current row to the bottom of the screen is then determined, if this is zero the current row is simply erased (0AECH). The row count is first used to scroll up the relevant section of LINTTB, the line termination table, by one byte. It is then used to scroll up the relevant section of the screen a row at a time. Starting at the row below the current row, each line is copied from the VDP Name Table into the LINWRK buffer (0BAAH) then copied back to the Name Table one row higher (0BC3H). Finally the lowest row on the screen is erased (0AECH).

Address... 0AB4H

This routine performs the ESC,"L" operation for the CHPDT standard routine control code processor. A CR operation is first performed to set the cursor column coordinate to the leftmost position. The number of rows from the current row to the bottom of the screen is then determined, if this is zero the current row is simply erased (0AECH). The row count is first used to scroll down the relevant section of LINTTB, the line termination table, by one byte. It is then used to scroll down the relevant section of the screen a row at a time. Starting at the next to last row of the screen, each line is copied from the VDP Name Table into the LINWRK buffer (0BAAH), then copied back to the Name Table one row lower (0BC3H). Finally the current row is erased (0AECH).

Address... 0AE3H

This routine is used to perform the DEL operation for the CHPUT standard routine control code processor. A LEFT operation is first performed. If this cannot be completed, because the cursor is already at the home position, then the routine terminates with no action. Otherwise a space is written to the VDP Name Table at the cursor's physical location (0BE6H).

Address... 0AECH

This routine performs the ESC,"l" operation for the CHPUT standard routine control code processor. The cursor column coordinate is set to 01H and control drops into the ESC,"K" routine.

4. ROM BIOS

Address... 0AEEH

This routine performs the ESC,"K" operation for the CHPHT standard routine control code processor. The row's entry in LINTTB, the line termination table, is first made non-zero to indicate that the logical line is not extended (0C29H). The cursor coordinates are converted to a physical address (0BF2H) in the VDP Name Table and the VDP set up for writes via the SETWRT standard routine. Spaces are then written directly to the VDP Data Port until the rightmost column, determined by LINLEN, is reached.

Address... 0B05H

This routine performs the ESC,"J" operation for the CHPUT standard routine control code processor. An ESC,"K" operation is performed on successive rows, starting with the current one, until the bottom of the screen is reached.

Address... 0B15H
Name..... ERAFNK
Entry..... None
Exit..... None
Modifies.. AF, DE, EI

Standard routine to turn the function key display off. CNSDFG is first zeroed and, if the VDP is in Graphics Mode or Multicolour Mode, the routine terminates with no further action. If the VDP is in 40x24 Text Mode or 32x24 Text Mode the last row on the screen is then erased (0AECH).

Address... 0B26H
Name..... FNKSB
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, EI

Standard routine to show the function key display if it is enabled. If CNSDFG is zero the routine terminates with no action, otherwise control drops into the DSPFNK standard routine..

Address... 0B2BH
Name..... DSPFNK
Entry..... None
Exit..... None
Modifies.. AF, BC, DE, EI

Standard routine to turn the function key display on. CNSDFG is set to FFH and, if the VDP is in Graphics Mode or Multicolour Mode, the routine terminates with no further action. Otherwise the cursor row coordinate is checked and, if the cursor is on the last row of the screen, a LF code (0AH) issued to the OUTDO standard routine to scroll the screen up.

4. ROM BIOS

Register pair HL is then set to point to either the unshifted or shifted function strings in the Workspace Area depending upon whether the SHIFT key is pressed. LINLEN has four subtracted, to allow a minimum of one space between fields, and is divided by five to determine the field size for each string. Successive characters are then taken from each function string, checked for graphic headers via the CNVCHR standard routine and placed in the LINWRK buffer until the string is exhausted or the zone is filled. When all five strings are completed the LINWRK buffer is written to the last row in the VDP Name Table (0BC3H).

Address... 0B9CH

This routine is used by the function key display related standard routines. The contents of register A are placed in CNSDFG then SCRMOD tested and Flag NC returned if the screen is in Graphics Mode or Multicolour Mode.

Address... 0BA5H

This routine copies eight bytes from the VDP VRAM into the LINWRK buffer, the VRAM physical address is supplied in register pair HL.

Address... 0BAAH

This routine copies a complete row of characters, with the length determined by LINLEN, from the VDP VRAM into the LINWRK buffer. The cursor row coordinate is supplied in register L.

Address... 0BBEH

This routine copies eight bytes from the LINWRK buffer into the VDP VRAM, the VRAM physical address is supplied in register pair HL.

Address... 0BC3H

This routine copies a complete row of characters, with the length determined by LINLEN, from the LINWRK buffer into the VDP VRAM. The cursor row coordinate is supplied in register L.

Address... 0BD8H

This routine reads a single byte from the VDP VRAM into register C. The column coordinate is supplied in register H, the row coordinate in register L.

Address... 0BE6H

This routine converts a pair of screen coordinates, the column in register H and the row in register L, into a physical address in the VDP Name Table. This address is returned in

4. ROM BIOS

register pair HL.

The row coordinate is first multiplied by thirty-two or forty, depending upon the screen mode, and added to the column coordinate. This is then added to the Name Table base address, taken from NAMBAS, to produce an initial address.

Because of the variable screen width, as contained in LINLEN, an additional offset has to be added to the initial address to keep the active region roughly centered within the screen. The difference between the "true" number of characters per row, thirty-two or forty, and the current width is halved and then rounded up to produce the left hand offset. For a UK machine, with a thirty-seven character width in 40x24 Text Mode, this will result in two unused characters on the left hand side and one on the right. The statement PRINT (41-WID)\2, where WID is any screen width, will display the left hand column offset in 40x24 Text Mode.

A complete BASIC program which emulates this routine is given below:

```
10 CPR=40:NAM=BASE(0):WID=PEEK(&HF3AE)
20 SCRMD=PEEK(&HFCAF):IF SCRMD=0 THEN 40
30 CPR=32:NAM=BASE(5):WID=PEEK(&HF3AF)
40 LH=(CPR+1-WID)\2
50 ADDR=NAM+(ROW-1)*CPR+(COL-1)+LH
```

This program is designed for the ROW and COL coordinate system used by the ROM BIOS where home is 1,1. Line 50 may be simplified, by removing the "-1" factors, if the BASIC Interpreter's coordinate system is to be used.

Address... 0C1DH

This routine calculates the address of a row's entry in LINTTB, the line termination table. The row coordinate is supplied in register L and the address returned in register pair DE.

Address... 0C29H

This routine makes a row's entry in LINTTB non-zero when entered at 0C29H and zero when entered at 0C2AH. The row coordinate is supplied in register L.

Address... 0C32H

This routine returns the number of rows on the screen in register A. It will normally return twenty-four if the function key display is disabled and twenty-three if it is enabled. Note that the screen size is determined by CRTCNT and may be modified with a BASIC statement, POKE &HF3B1H,14:SCREEN 0 for example.

4. ROM BIOS

```

Address... 0C3CH
Name..... KEYINT
Entry..... None
Exit..... None
Modifies.. EI

```

Standard routine to process Z80 interrupts, these are generated by the VDP once every 20 ms on a UK machine. The VDP Status Register is first read and bit 7 checked to ensure that this is a frame rate interrupt, if not the routine terminates with no action. The contents of the Status Register are saved in STATFL and bit 5 checked for sprite coincidence. If the Coincidence Flag is active then the relevant entry in TRPTBL is updated (0EF1H).

INTCNT, the "INTERVAL" counter, is then decremented. If this has reached zero the relevant entry in TRPTBL is updated (0EF1H) and the counter reset with the contents of INTVAL.

JIFFY, the "TIME" counter, is then incremented. This counter just wraps around to zero when it overflows.

MUSICF is examined to determine whether any of the three music queues generated by the "PLAY" statement are active. For each active queue the dequeueing routine (113BH) is called to fetch the next music packet and write it to the PSG.

SCNCNT is then decremented to determine if a joystick and keyboard scan is required, if not the interrupt handler terminates with no further action. This counter is used to increase throughput and to minimize keybounce problems by ensuring that a scan is only carried out every three interrupts. Assuming a scan is required joystick connector 1 is selected and the two Trigger bits read (120CH), followed by the two Trigger bits from joystick connector 2 (120CH) and the SPACE key from row 8 of the keyboard (1226H). These five inputs, which are all related to the "STRIG" statement, are combined into a single byte where 0=Pressed, 1=Not pressed:

Figure 35: "STRIG" Inputs

This reading is compared with the previous one, held in TRGFLG, to produce an active transition byte and TRGFLG is updated with the new reading. The active transition byte is normally zero but contains a 1 in each position where a transition from unpressed to pressed has occurred. This active transition byte

4. ROM BIOS

is shifted out bit by bit and the relevant entry in TRPTBL updated (0EF1H) for each active device.

A complete scan of the keyboard matrix is then performed to identify new key depressions, any found are translated into key codes and placed in KEYBUF (0D12H). If KEYBUF is found to be empty at the end of this process REPCNT is decremented to see whether the auto-repeat delay has expired, if not the routine terminates. If the delay period has expired REPCNT is reset with the fast repeat value (60 ms), the OLDKEY keyboard map is reinitialized and the keyboard scanned again (0D4EH). Any keys which are continuously pressed will show up as new transitions during this scan. Note that keys will only auto-repeat while an application program keeps KEYBUF empty by reading characters. The interrupt handler then terminates.

Address... 0D12H

This routine performs a complete scan of all eleven rows of the keyboard matrix for the interrupt handler. Each of the eleven rows is read in via the PPI and placed in ascending order in NEWKEY. ENSTOP is then checked to see if warm starts are enabled. If its contents are non-zero and the keys CODE, GRAPH, CTRL and SHIFT are pressed control transfers to the BASIC Interpreter (409BH) via the CALBAS standard routine. This facility is useful as even a machine code program can be terminated as long as the interrupt handler is running. The contents of NEWKEY are compared with the previous scan contained in OLDKEY. If any change at all has occurred REPCNT is loaded with the initial auto-repeat delay (780 ms). Each row 1, reading from NEWKEY is then compared with the previous one, held in OLDKEY, to produce an active transition byte and OLDKEY is updated with the new reading. The active transition byte is normally zero but contains a 1 in each position where a transition from unpressed to pressed has occurred. If the row contains any transitions these are decoded and placed in KEYBUF as key codes (0D89H). When all eleven rows have been completed the routine checks whether there are any characters in KEYBUF, by subtracting GETPNT from PUTPNT, and terminates.

Address... 0D6AH
Name..... CHSNS
Entry..... None
Exit..... Flag NZ if characters in KEYBUF
Modifies.. AF, EI

Standard routine to check if any keyboard characters are ready. If the screen is in Graphics Mode or Multicolour Mode then GETPNT is subtracted from PUTPNT (0D62H) and the routine terminates. If the screen is in 40x24 Text Mode or 32x24 Text Mode the state of the SHIFT key is also examined and the function key display updated, via the DSPFNK standard routine, if it has changed.

4. ROM BIOS

The key number is then converted into a key code and placed in KEYBUF (1021H). When all eight possible bits have been processed the routine terminates.

Address... 0DA5H

This table contains the key codes of key numbers 00H to 2FH for various combinations of the control keys. A zero entry in the table means that no key code will be produced when that key is pressed:

	37H	36H	35H	34H	33H	32H	31H	30H	Row	0
	3BH	5DH	5BH	5CH	3DH	2DH	39H	38H	Row	1

4. ROM BIOS

Address... 0EC5H

Control transfers to this routine, from 0FC3H, to complete decoding of the five function keys. The relevant entry in FNKFLG is first checked to determine whether the key is associated with an "ON KEY GOSUB" statement. If so, and provided that CURLIN shows the BASIC Interpreter to be in program mode, the relevant entry in TRPTBL is updated (0EF1H) and the routine terminates. If the key is not tied to an "ON KEY GOSUB" statement, or if the Interpreter is in direct mode, the string of characters associated with the function key is returned instead. The key number is multiplied by sixteen, as each string is sixteen characters long, and added to the starting address of the function key strings in the Workspace Area. Sequential characters are then taken from the string and placed in KEYBUF (0F55H) until the zero byte terminator is reached.

Address... 0EF1H

This routine is used to update a device's entry in TRPTBL when it has produced a BASIC program interrupt. On entry register pair HL points to the device's status byte in the table. Bit 0 of the status byte is checked first, if the device is not "ON" then the routine terminates with no action. Bit 2, the event flag, is then checked. If this is already set then the routine terminates, otherwise it is set to indicate that an event has occurred. Bit 1, the "STOP" flag, is then checked. If the device is stopped then the routine terminates with no further action. Otherwise ONGSBF is incremented to signal to the Interpreter Runloop that the event should now be processed.

Address... 0F06H

This section of the key decoder processes the HOME key only. The state of the SHIFT key is determined via row 6 of NEWKEY and the key code for HOME (0BH) or CLS (0CH) placed in KEYBUF (0F55H) accordingly.

Address... 0F10H

This section of the keyboard decoder processes key numbers 30H to 57H apart from the CAP, F1 to F5, STOP and HOME keys. The key number is simply used to look up the key code in the table at 1033H and this is then placed in KEYBUF (0F55H).

Address... 0F1FH

This section of the keyboard decoder processes the DEAD key found on European MSX machines. On UK machines the key in row 2, column 5 always generates the pound key code (9CH) shown in the table at 0DA5H. On European machines this table will have the key code FFH in the same locations. This key code only serves as a flag to indicate that the next key pressed, if it

4. ROM BIOS

is a vowel, should be modified to produce an accented graphics character.

The state of the SHIFT and CODE keys is determined via row 6 of NEWKEY and one of the following placed in KANAST: 01H=DEAD, 02H=DEAD+SHIFT, 03H=DEAD+CODE, 04H=DEAD+SHIFT+CODE.

Address... 0F36H

This section of the keyboard decoder processes the CAP key. The current state of CAPST is inverted and control drops into the CHGCAP standard routine.

Address... 0F3DH
Name..... CHGCAP
Entry..... A=ON/OFF Switch
Exit..... None
Modifies.. AF

Standard routine to turn the Caps Lock LED on or off as determined by the contents of register A: 00H=On, NZ=Off. The LED is modified using the bit set/reset facility of the PPI Mode Port. As CAPST is not changed this routine does not affect the characters produced by the keyboard.

Address... 0F46H

This section of the keyboard decoder processes the STOP key. The state of the CTRL key is determined via row 6 of NEWKEY and the key code for STOP (04H) or CTRL/STOP (03H) produced as appropriate. If the CTRL/STOP code is produced it is copied to INTFLG, for use by the ISCNTC standard routine, and then placed in KEYBUF (0F55H). If the STOP code is produced it is also copied to INTFLG but is not placed in KEYBUF, instead only a click is generated (0F64H). This means that an application program cannot read the STOP key code via the ROM BIOS standard routines.

Address... 0F55H

This section of the keyboard decoder places a key code in KEYBUF and generates an audible click. The correct address in the keyboard buffer is first taken from PUTPNT and the code placed there. The address is then incremented (105BH). If it has wrapped round and caught up with GETPNT then the routine terminates with no further action as the keyboard buffer is full. Otherwise PUTPNT is updated with the new address.

CLIKSW and CLIKFL are then both checked to determine whether a click is required. CLIKSW is a general enable/disable switch while CLIKFL is used to prevent multiple clicks when the function keys are pressed. Assuming a click is required the Key Click output is set via the PPI Mode Port and, after a delay of 50 μ s, control drops into the CHGSND standard routine.

4. ROM BIOS

Address... 0F7AH
Name..... CHGSND
Entry..... A=ON/OFF Switch
Exit..... None
Modifies.. AF

Standard routine to set or reset the Key Click output via the PPI Mode Port: 00H=Reset, NZ=Set. This audio output is AC coupled so absolute polarities should not be taken too seriously.

Address... 0F83H

This section of the keyboard decoder processes key numbers 00H to 2FH. The state of the SHIFT, GRAPH and CODE keys is determined via row 6 of NEWKEY and combined with the key number to form a look-up address into the table at ODA5H. The key code is then taken from the table. If it is zero the routine terminates with no further action, if it is FFH control transfers to the DEAD key processor (0F1FH). If the code is in the range 40H to 5FH or 60H to 7FH and the CTRL key is pressed then the corresponding control code is placed in KEYBUF (0F55H). If the code is in the range 01H to 1FH then a graphic header code (01H) is first placed in KEYBUF (0F55H) followed by the code with 40H added. If the code is in the range 61H to 7BH and CAPST indicates that caps lock is on then it is converted to upper case by subtracting 20H. Assuming that KANAST contains zero, as it always will on UK machines, then the key code is placed in KEYBUF (0F55H) and the routine terminates. On European MSX machines, with a DEAD key instead of a pound key, then the key codes corresponding to the vowels a, e, i, o, u may be further modified into graphics codes.

Address... 0FC3H

This section of the keyboard decoder processes the five function keys. The state of the SHIFT key is examined via row 6 of NEWKEY and five added to the key number if it is pressed. Control then transfers to 0EC5H to complete processing.

Address... 1021H

This routine searches the table at 1B97H to determine which group of keys the key number supplied in register C belongs to. The associated address is then taken from the table and control transferred to that section of the keyboard decoder. Note that the table itself is actually patched into the middle of the OUTDO standard routine as a result of the modifications made to the Japanese ROM.

Address... 1033H

This table contains the key codes of key numbers 30H to 57H other than the special keys CAP, F1 to F5, STOP and HOME. A

4. ROM BIOS

zero entry in the table means that no key code will be produced when that key is pressed:

00H	00H	00H	00H	00H	00H	00H	00H	00H	Row 6
0DH	18H	08H	00H	09H	1BH	00H	00H	00H	Row 7
1CH	1FH	1EH	1DH	7FH	12H	0CH	20H	00H	Row 8
34H	33H	32H	31H	30H	00H	00H	00H	00H	Row 9
2EH	2CH	2DH	39H	38H	37H	36H	35H	00H	Row 10
7	6	5	4	3	2	1	0	Column	

Address... 105BH

This routine simply zeroes KANAST and then transfers control to 10C2H.

Address... 1061H

This table contains the graphics characters which replace the vowels a, e, i, o, u on European machines.

Address... 10C2H

This routine increments the keyboard buffer pointer, either PUTPNT or GETPNT, supplied in register pair HL. If the pointer then exceeds the end of the keyboard buffer it is wrapped back to the beginning.

Address... 10CBH

Name..... CHGET

Entry..... None

Exit..... A=Character from keyboard

Modifies.. AF, EI

Standard routine to fetch a character from the keyboard buffer. The buffer is first checked to see if already contains a character (0D6AH). If not the cursor is turned on (09DAH), the buffer checked repeatedly until a character appears (0D6AH) and then the cursor turned off (0A27H). The character is taken from the buffer using GETPNT which is then incremented (10C2H).

Address... 10F9H

Name..... CKCNTC

Entry..... None

Exit..... None

Modifies.. AF, EI

Standard routine to check whether the CTRL-STOP or STOP keys have been pressed. It is used by the BASIC Interpreter inside processor-intensive statements, such as "WAIT" and "CIRCLE", to check for program termination. Register pair HL is first zeroed and then control transferred to the ISCNTC standard routine. When the Interpreter is running register pair HL normally contains the address of the current character in the BASIC

4. ROM BIOS

program text. If ISCNTC is CTRL-STOP terminated this address will be placed in OLDTEXT by the "STOP" statement handler (63E6H) for use by a later "CONT" statement. Zeroing register pair HL beforehand signals to the "CONT" handler that termination occurred inside a statement and it will issue a "Can't CONTINUE" error if continuation is attempted.

Address... 1102H
Name..... WRTPSG
Entry..... A=Register number, E=Data byte
Exit..... None
Modifies.. EI

Standard routine to write a data byte to any of the sixteen PSG registers. The register selection number is written to the PSG Address Port and the data byte written to the PSG Data Write Port.

Address... 110EH
Name..... RDPSG
Entry..... A=Register number
Exit..... A=Data byte read from PSG
Modifies.. A

Standard routine to read a data byte from any of the sixteen PSG registers. The register selection number is written to the PSG Address Port and the data byte read from the PSG Data Read Port.

Address... 1113H
Name..... BEEP
Entry..... None
Exit..... None
Modifies.. AF, BC, E, EI

Standard routine to produce a beep via the PSG. Channel A is set to produce a tone of 1316Hz then enabled with an amplitude of seven. After a delay of 40 ms control transfers to the GICINI standard routine to reinitialize the PSG.

Address... 113BH

This routine is used by the interrupt handler to service a music queue. As there are three of these, each feeding a PSG channel, the queue to be serviced is specified by supplying its number in register A: 0=VOICAQ, 1=VOICBQ and 2=VOICCQ.

Each string in a "PLAY" statement is translated into a series of data packets by the BASIC Interpreter. These are placed in the appropriate queue followed by an end of data byte (FFH). The task of dequeuing the packets, decoding them and setting the PSG is left to the interrupt handler. The Interpreter is thus free to proceed immediately to the next statement without having to wait for notes to finish.

4. ROM BIOS

The first two bytes of any packet specify its byte count and duration. The three most significant bits of the first byte specify the number of bytes following the header in the packet. The remainder of the header specifies the event duration in 20 ms units. This duration count determines how long it will be before the next packet is read from the queue.

Figure 37: Packet Header

The packet header may be followed by zero or more blocks, in any order, containing frequency or amplitude information:

Figure 38: Packet Block Types

The routine first locates the current duration counter in the relevant voice buffer (VCBA, VCBB or VCBC) via the GETVCP

4. ROM BIOS

standard routine and decrements it. If the counter has reached zero then the next packet must be read from the queue, otherwise the routine terminates.

The queue number is placed in QUEUEN and a byte read from the queue (11E2H). This is then checked to see if it is the end of data mark (FFH), if so the queue terminates (11B0H). Otherwise the byte count is placed in register C and the duration MSB in the relevant voice buffer. The second byte is read (11E2H) and the duration LSB placed in the relevant voice buffer. The byte count is then examined, if there are no bytes to follow the packet header the routine terminates. Otherwise successive bytes are read from the queue, and the appropriate action taken, until the byte count is exhausted.

If a frequency block is found then a second byte is read and both bytes written to PSG Registers 0 and 1, 2 and 3 or 4 and 5 depending on the queue number.

If an amplitude block is found the Amplitude and Mode bits are written to PSG Registers 8, 9 or 10 depending on the queue number. If the Mode bit is 1, selecting modulated rather than fixed amplitude, then the byte is also written to PSG Register 13 to set the envelope shape.

If an envelope block is found, or if bit 6 of an amplitude block is set, then a further two bytes are read from the queue and written to PSG Registers 11 and 12.

Address... 11B0H

This routine is used when an end of data mark (FFH) is found in one of the three music queues. An amplitude value of zero is written to PSG Register 8 9 or 10, depending on the queue number, to shut the channel down. The channel's bit in MUSICF is then reset and control drops into the STRTMS standard routine.

Address... 11C4H
Name..... STRTMS
Entry..... None
Exit..... None
Modifies.. AF, HL

Standard routine used by the "PLAY" statement handler to initiate music dequeuing by the interrupt handler. MUSICF is first examined, if any channels are already running the routine terminates with no action. PLYCNT is then decremented, if there are no more "PLAY" strings queued up the routine terminates. Otherwise the three duration counters, in VCBA, VCBB and VCBC, are set to 0001H, so that the first packet of the new group will be dequeued at the next interrupt, and MUSICF is set to 07H to enable all three channels.

4. ROM BIOS

Address... 11E2H

This routine loads register A with the current queue number, from QUEUEN, and then reads a byte from that queue (14ADH).

Address... 11EEH
Name..... GTSTCK
Entry..... A=Joystick ID (0, 1 or 2)
Exit..... A=Joystick position code
Modifies.. AF, B, DE, HL, EI

Standard routine to read the position of a joystick or the four cursor keys. If the supplied ID is zero the state of the cursor keys is read via PPI Port B (1226H) and converted to a position code using the look-up table at 1243H. Otherwise joystick connector 1 or 2 is read (120CH) and the four direction bits converted to a position code using the look-up table at 1233H. The returned position codes are:

Address... 120CH

This routine reads the joystick connector specified by the contents of register A: 0=Connector 1, 1=Connector 2. The current contents of PSG Register 15 are read in then written back with the Joystick Select bit appropriately set. PSG Register 14 is then read into register A (110CH) and the routine terminates.

Address... 1226H

This routine reads row 8 of the keyboard matrix. The current contents of PPI Port C are read in then written back with the four Keyboard Row Select bits set for row 8. The column inputs are then read into register A from PPI Port B.

Address... 1253H
Name..... GTTRIG
Entry..... A=Trigger ID (0, 1, 2, 3 or 4)
Exit..... A=Status code
Modifies.. AF, BC, EI

Standard routine to check the joystick trigger or space key status. If the supplied ID is zero row 8 of the keyboard matrix is read (1226H) and converted to a status code. Otherwise

4. ROM BIOS

joystick connector 1 or 2 is read (120CH) and converted to a status code. The selection IDs are:

```
0=SPACE KEY
1=JOY 1, TRIGGER A
2=JOY 2, TRIGGER A
3=JOY 1, TRIGGER B
4=JOY 2, TRIGGER B
```

The value returned is FFH if the relevant trigger is pressed and zero otherwise.

```
Address... 1273H
Name..... GTPDL
Entry..... A=Paddle ID (1 to 12)
Exit..... A=Paddle value (0 to 255)
Modifies.. AF, BC, DE, EI
```

Standard routine to read the value of any paddle attached to a joystick connector. Each of the six input lines (four direction plus two triggers) per connector can support a paddle so twelve are possible altogether. The paddles attached to joystick connector 1 have entry identifiers 1, 3, 5, 7, 9 and 11. Those attached to joystick connector 2 have entry identifiers 2, 4, 6, 8, 10 and 12. Each paddle is basically a one-shot pulse generator, the length of the pulse being controlled by a variable resistor. A start pulse is issued to the specified joystick connector via PSG Register 15. A count is then kept of how many times PSG Register 14 has to be read until the relevant input times out. Each unit increment represents an approximate period of 12 µs on an MSX machine with one wait state.

```
Address... 12ACH
Name..... GTPAD
Entry..... A=Function code (0 to 7)
Exit..... A=Status or value
Modifies.. AF, BC, DE, HL, EI
```

Standard routine to access a touchpad attached to either of the joystick connectors. Available functions codes for joystick connector 1 are:

```
0=Return Activity Status
1=Return "X" coordinate
2=Return "Y" coordinate
3=Return Switch Status
```

Function codes 4 to 7 have the same effect with respect to joystick connector 2. The Activity Status function returns FFH if the Touchpad is being touched and zero otherwise. The Switch Status function returns FFH if the switch is being pressed and zero otherwise. The two coordinate request functions return the coordinates of the last location touched. These coordinates are

4. ROM BIOS

actually stored in the Workspace Area variables PADX and PADY when a call with function code 0 or 4 detects activity. Note that these variables are shared by both joystick connectors.

```
Address... 1384H
Name..... STMOTR
Entry..... A=Motor ON/OFF code
Exit..... None
Modifies.. AF
```

Standard routine to turn the cassette motor relay on or off via PPI Port C: 00H=Off, 01H=On, FFH=Reverse current state.

```
Address... 1398H
Name..... NMI
Entry..... None
Exit..... None
Modifies.. None
```

Standard routine to process a Z80 Non Maskable Interrupt, simply returns on a standard MSX machine.

```
Address... 139DH
Name..... INIFNK
Entry..... None
Exit..... None
Modifies.. BC, DE, HL
```

Standard routine to initialize the ten function key strings to their power-up values. The one hundred and sixty bytes of data commencing at 13A9H are copied to the FNKSTR buffer in the Workspace Area.

```
Address... 13A9H
```

This area contains the power-up strings for the ten function keys. Each string is sixteen characters long, unused positions contain zeroes:

```
F1 to F5  F6 to F10
color      color 15,4,4 CR
auto       cload"
goto       cont CR
list       list. CR UP UP
run CR     run CLS CR
```

```
Address... 1449H
Name..... RDVDP
Entry..... None
Exit..... A=VDP Status Register contents
Modifies.. A
```

Standard routine to input the contents of the VDP Status Register by reading the Command Port. Note that reading the VDP

4. ROM BIOS

Status Register will clear the associated flags and may affect the interrupt handler.

Address... 144CH
Name..... RSLREG
Entry..... None
Exit..... A=Primary Slot Register contents
Modifies.. A

Standard routine to input the contents of the Primary slot Register by reading PPI Port A.

Address... 144FH
Name..... WSLREG
Entry..... A=Value to write
Exit..... None
Modifies.. None

Standard routine to set the Primary Slot Register by writing to PPI Port A.

Address... 1452H
Name..... SNSMAT
Entry..... A=Keyboard row number
Exit..... A=Column data of keyboard row
Modifies.. AF, C, EI

Standard routine to read a complete row of the keyboard matrix. PPI Port C is read in then written back with the row number occupying the four Keyboard Row Select bits. PPI Port B is then read into register A to return the eight column inputs. The four miscellaneous control outputs of PPI Port C are unaffected by this routine.

Address... 145FH
Name..... ISFLIO
Entry..... None
Exit..... Flag NZ if file I/O active
Modifies.. AF

Standard routine to check whether the BASIC Interpreter is currently directing its input or output via an I/O buffer. This is determined by examining PTRFIL. It is normally zero but will contain a buffer FCB (File Control Block) address while statements such as "PRINT#1", "INPUT#1", etc. are being executed by the Interpreter.

Address... 146AH
Name..... DCOMPR
Entry..... HL, DE
Exit..... Flag NC if HL>DE, Flag Z if HL=DE, Flag C if HL<DE
Modifies.. AF

Standard routine used by the BASIC Interpreter to check the

4. ROM BIOS

relative values of register pairs HL and DE.

Address... 1470H
Name..... GETVCP
Entry..... A=Voice number (0, 1, 2)
Exit..... HL=Address in voice buffer
Modifies.. AF, HL

Standard routine to return the address of byte 2 in the specified voice buffer (VCBA, VCBB or VCBC).

Address... 1474H
Name..... GETVC2
Entry..... L=Byte number (0 to 36)
Exit..... HL=Address in voice buffer
Modifies.. AF, HL

Standard routine to return the address of any byte in the voice buffer (VCBA, VCBB or VCBC) specified by the voice number in VOICEN.

Address... 148AH
Name..... PHYDIO
Entry..... None
Exit..... None
Modifies.. None

Standard routine for use by Disk BASIC, simply returns on standard MSX machines.

Address... 148EH
Name..... FORMAT
Entry..... None
Exit..... None
Modifies.. None

Standard routine for use by Disk BASIC, simply returns on standard MSX machines.

Address... 1492H
Name..... PUTQ
Entry..... A=Queue number, E=Data byte
Exit..... Flag Z if queue full
Modifies.. AF, BC, HL

Standard routine to place a data byte in one of the three music queues. The queue's get and put positions are first taken from QUETAB (14FAH). The put position is temporarily incremented and compared with the get position, if they are equal the routine terminates as the queue is full. Otherwise the queue's address is taken from QUETAB and the put position added to it. The data byte is placed at this location in the queue, the put position is incremented and the routine terminates. Note that the music queues are circular, if the get

4. ROM BIOS

or put pointers reach the last position in the queue they wrap around back to the start.

Address... 14ADH

This routine is used by the interrupt handler to read a byte from one of the three music queues. The queue number is supplied in register A, the data byte is returned in register A and the routine returns Flag Z if the queue is empty. The queue's get and put positions are first taken from QUETAB (14FAH). If the putback flag is active then the data byte is taken from QUEBAK and the routine terminates (14D1H), this facility is unused in the current versions of the MSX ROM. The put position is then compared with the get position, if they are equal the routine terminates as the queue is empty. Otherwise the queue's address is taken from QUETAB and the get position added to it. The data byte is read from this location in the queue, the get position is incremented and the routine terminates.

Address... 14DAH

This routine is used by the GICINI standard routine to initialize a queue's control block in QUETAB. The control block is first located in QUETAB (1504H) and the put, get and putback bytes zeroed. The size byte is set from register B and the queue address from register pair DE.

Address... 14EBH
Name..... LFTQ
Entry..... A=Queue number
Exit..... HL=Free space left in queue
Modifies.. AF, BC, HL

Standard routine to return the number of free bytes left in a music queue. The queue's get and put positions are taken from QUETAB (14FAH) and the free space determined by subtracting put from get.

Address... 14FAH

This routine returns a queue's control parameters from QUETAB, the queue number is supplied in register A. The control block is first located in QUETAB (1504H), the put position is then placed in register B, the get position in register C and the putback flag in register A.

Address... 1504H

This routine locates a queue's control block in QUETAB. The queue number is supplied in register A and the control block address returned in register pair HL. The queue number is simply multiplied by six, as there are six bytes per block, and added to the address of QUETAB as held in QUEUES.

4. ROM BIOS

Address... 1510H
Name..... GRPPRT
Entry..... A=Character
Exit..... None
Modifies.. EI

Standard routine to display a character on the screen in either Graphics Mode or Multicolour Mode, it is functionally equivalent to the CHPUT standard routine.

The CNVCHR standard routine is first used to check for a graphic character, if the character is a header code (01H) then the routine terminates with no action. If the character is a converted graphic one then the control code decoding section is skipped. Otherwise the character is checked to see if it is a control code. Only the CR code (0DH) is recognized (157EH), all other characters smaller than 20H are ignored.

Assuming the character is displayable its eight byte pixel pattern is copied from the ROM character set into the PATWRK buffer (0752H) and FORCLR copied to ATRBYT to set its colour. The current graphics coordinates are then taken from GRPACX and GRPACY and used to set the current pixel physical address via the SCALXY and MAPXYC standard routines.

The eight byte pattern in PATWRK is processed a byte at a time. At the start of each byte the current pixel physical address is obtained via the FETCHC standard routine and saved. The eight bits are then examined in turn. If the bit is a 1 the associated pixel is set by the SETC standard routine, if it is a 0 no action is taken. After each bit the current pixel physical address is moved right (16ACH). When the byte is finished, or the right hand edge of the screen is reached, the initial current pixel physical address is restored and moved down one position by the TDOWNC standard routine.

When the pattern is complete, or the bottom of the screen has been reached, GRPACX is updated. In Graphics Mode its value is increased by eight, in Multicolour Mode by thirty-two. If GRPACX then exceeds 255, the right hand edge of the screen, a CR operation is performed (157EH).

Address... 157EH

This routine performs the CR operation for the GRPPRT standard routine, this code functions as a combined CR,LF. GRPACX is zeroed and eight or thirty-two, depending on the screen mode, added to GRPACY. If GRPACY then exceeds 191, the bottom of the screen, it is set to zero.

GRPACX and GRPACY may be manipulated directly by an application program to compensate for the limited number of control functions available.

4. ROM BIOS

Address... 1599B
Name..... SCALXY
Entry..... BC=X coordinate, DE=Y coordinate
Exit..... Flag NC if clipped
Modifies.. AF

Standard routine to clip a pair of graphics coordinates if necessary. The BASIC Interpreter can produce coordinates in the range -32768 to +32767 even though this far exceeds the actual screen size. This routine modifies excessive coordinate values to fit within the physically realizable range. If the X coordinate is greater than 255 it is set to 255, if the Y coordinate is greater than 191 it is set to 191. If either coordinate is negative (greater than 7FFFH) it is set to zero. Finally if the screen is in Multicolour Mode both coordinates are divided by four as required by the MAPXYC standard routine.

Address... 15D9H

This routine is used to check the current screen mode, it returns Flag Z if the screen is in Graphics Mode.

Address... 15DFH
Name..... MAPXYC
Entry..... BC=X coordinate, DE=Y coordinate
Exit..... None
Modifies.. AF, D, HL

Standard routine to convert a graphics coordinate pair into the current pixel physical address. The location in the Character Pattern Table of the byte containing the pixel is placed in CLOC. The bit mask identifying the pixel within that byte is placed in CMASK. Slightly different conversion methods are used for Graphics Mode and Multicolour Mode, equivalent programs in BASIC are:

Graphics Mode

```
10 INPUT "X,Y Coordinates";X,Y
20 A=(Y\8)*256+(Y AND 7)+(X AND &HF8)
30 PRINT "ADDR=";HEX$(Base(12)+A);"H ";
40 RESTORE 100
50 FOR N=0 TO (X AND 7):READ M$: NEXT N
60 PRINT "MASK=";M$
70 GOTO 10
100 DATA 10000000
110 DATA 01000000
120 DATA 00100000
130 DATA 00010000
140 DATA 00001000
150 DATA 00000100
160 DATA 00000010
170 DATA 00000001
```

4. ROM BIOS

Multicolour Mode

```
10 INPUT "X,Y Coordinates";X,Y
20 X=X\4:Y=Y\4
30 A=(Y\8)*256+(Y AND 7)+(X*4 AND &HF8)
40 PRINT "ADDR=";HEX$(BASE(17)+A);"H ";
50 IF X MOD 2=0 THEN MS="11110000" ELSE MS="00001111"
60 PRINT "MASK=";M$
70 GOTO 10
```

The allowable input range for both programs is X=0 to 255 and Y=0 to 191. The data statements in the Graphics Mode program correspond to the eight byte mask table commencing at 160BH in the MSX ROM. Line 20 in the Multicolour Mode program actually corresponds to the division by four in the SCALXY standard routine. It is included to make the coordinate system consistent for both programs.

```
Address... 1639H
Name..... FETCHC
Entry..... None
Exit..... A=CMASK, HL=CLOC
Modifies.. A, HL
```

Standard routine to return the current pixel physical address, register pair HL is loaded from CLOC and register A from CMASK.

```
Address... 1640H
Name..... STOREC
Entry..... A=CMASK, HL=CLOC
Exit..... None
Modifies.. None
```

Standard routine to set the current pixel physical address, register pair HL is copied to CLOC and register A is copied to CMASK.

```
Address... 1647H
Name..... READC
Entry..... None
Exit..... A=Colour code of current pixel
Modifies.. AF, EI
```

Standard routine to return the colour of the current pixel. The VRAM physical address is first obtained via the FETCHC standard routine. If the screen is in Graphics Mode the byte pointed to by CLOC is read from the Character Pattern Table via the RDVRM standard routine. The required bit is then isolated by CMASK and used to select either the upper or lower four bits of the corresponding entry in the Colour Table.

If the screen is in Multicolour Mode the byte pointed to by CLOC is read from the Character Pattern Table via the RDVRM

4. ROM BIOS

standard routine. CMASK is then used to select either the upper or lower four bits of this byte. The value returned in either case will be a normal VDP colour code from zero to fifteen.

```
Address... 1676H
Name..... SETATR
Entry..... A=Colour code
Exit..... Flag C if illegal code
Modifies.. Flags
```

Standard routine to set the graphics ink colour used by the SETC and NSETCX standard routines. The colour code, from zero to fifteen, is simply placed in ATRBYT.

```
Address... 167EH
Name..... SETC
Entry..... None
Exit..... None
Modifies.. AF, EI
```

Standard routine to set the current pixel to any colour, the colour code is taken from ATRBYT. The pixel's VRAM physical address is first obtained via the FETCHC standard routine. In Graphics Mode both the Character Pattern Table and Colour Table are then modified (186CH).

In Multicolour Mode the byte pointed to by CLOC is read from the Character Pattern Table by the RDVRM standard routine. The contents of ATRBYT are then placed in the upper or lower four bits, as determined by CMASK, and the byte written back via the WRTVRM standard routine

```
Address... 16ACH
```

This routine moves the current pixel physical address one position right. If the right hand edge of the screen is exceeded it returns with Flag C and the physical address is unchanged. In Graphics Mode CMASK is first shifted one bit right, if the pixel still remains within the byte the routine terminates. If CLOC is at the rightmost character cell (LSB=F8H to FFH) then the routine terminates with Flag C (175AH). Otherwise CMASK is set to 80H, the leftmost pixel, and 0008H added to CLOC.

In Multicolour Mode control transfers to a separate routine (1779H).

```
Address... 16C5H
Name..... RIGHTC
Entry..... None
Exit..... None
Modifies.. AF
```

Standard routine to move the current pixel physical address

4. ROM BIOS

one position right. In Graphics Mode CMASK is first shifted one bit right, if the pixel still remains within the byte the routine terminates. Otherwise CMASK is set to 80H, the leftmost pixel, and 0008H added to CLOC. Note that incorrect addresses will be produced if the right hand edge of the screen is exceeded.

In Multicolour Mode control transfers to a separate routine (178BH).

Address... 16D8H

This routine moves the current pixel physical address one position left. If the left hand edge of the screen is exceeded it returns Flag C and the physical address is unchanged. In Graphics Mode CMASK is first shifted one bit left, if the pixel still remains within the byte the routine terminates. If CLOC is at the leftmost character cell (LSB=00H to 07H) then the routine terminates with Flag C (175AH). Otherwise CMASK is set to 01H, the rightmost pixel, and 0008H subtracted from CLOC.

In Multicolour Mode control transfers to a separate routine (179CH).

Address... 16EEH
Name..... LEFTC
Entry..... None
Exit..... None
Modifies.. AF

Standard routine to move the current pixel physical address one position left. In Graphics Mode CMASK is first shifted one bit left, if the pixel still remains within the byte the routine terminates. Otherwise CMASK is set to 01H, the leftmost pixel, and 0008H subtracted from CLOC. Note that incorrect addresses will be produced if the left hand edge of the screen is exceeded.

In Multicolour Mode control transfers to a separate routine (17ACH).

Address... 170AH
Name..... TDOWNC
Entry..... None
Exit..... Flag C if off screen
Modifies.. AF

Standard routine to move the current pixel physical address one position down. If the bottom edge of the screen is exceeded it returns Flag C and the physical address is unchanged. In Graphics Mode CLOC is first incremented, if it still remains within an eight byte boundary the routine terminates. If CLOC was in the bottom character row (CLOC>=1700H) then the routine terminates with Flag C (1759H). Otherwise 00F8H is added to

4. ROM BIOS

CLOC.

In Multicolour Mode control transfers to a separate routine (17C6H).

Address... 172AH
Name..... DOWNC
Entry..... None
Exit..... None
Modifies.. AF

Standard routine to move the current pixel physical address one position down. In Graphics Mode CLOC is first incremented, if it still remains within an eight byte boundary the routine terminates. Otherwise 00F8H is added to CLOC. Note that incorrect addresses will be produced if the bottom edge of the screen is exceeded.

In Multicolour Mode control transfers to a separate routine (17DCH).

Address... 173CH
Name..... TUPC
Entry..... None
Exit..... Flag C if off screen
Modifies.. AF

Standard routine to move the current pixel physical address one position up. If the top edge of the screen is exceeded it returns with Flag C and the physical address is unchanged. In Graphics Mode CLOC is first decremented, if it still remains within an eight byte boundary the routine terminates. If CLOC was in the top character row (CLOC<0100H) then the routine terminates with Flag C. Otherwise 00F8H is subtracted from CLOC.

In Multicolour Mode control transfers to a separate routine (17E3H).

Address... 175DH
Name..... UPC
Entry..... None
Exit..... None
Modifies.. AF

Standard routine to move the current pixel physical address one position up. In Graphics Mode CLOC is first decremented, if it still remains within an eight byte boundary the routine terminates. Otherwise 00F8H is subtracted from CLOC. Note that incorrect addresses will be produced if the top edge of the screen is exceeded.

In Multicolour Mode control transfers to a separate routine (17F8H).

4. ROM BIOS

Address... 1779H

This is the Multicolour Mode version of the routine at 16ACH. It is identical to the Graphics Mode version except that CMASK is shifted four bit positions right and becomes F0H if a cell boundary is crossed.

Address... 178BH

This is the Multicolour Mode version of the RIGHTC standard routine. It is identical to the Graphics Mode version except that CMASK is shifted four bit positions right and becomes F0H if a cell boundary is crossed.

Address... 179CH

This is the Multicolour Mode version of the routine at 16D8H. It is identical to the Graphics Mode version except that CMASK is shifted four bit positions left and becomes 0FH if a cell boundary is crossed.

Address... 17ACH

This is the Multicolour Mode version of the LEFTC standard routine. It is identical to the Graphics Mode version except that CMASK is shifted four bit positions left and becomes 0FH if a cell boundary is crossed.

Address... 17C6H

This is the Multicolour Mode version of the TDOWNC standard routine. It is identical to the Graphics Mode version except that the bottom boundary address is 0500H instead of 1700H. There is a bug in this routine which will cause it to behave unpredictably if MLTCGP, the Character Pattern Table base address, is changed from its normal value of zero. There should be an EX DE,HL instruction inserted at address 17CEH.

If the Character Pattern Table base is increased the routine will think it has reached the bottom of the screen when it actually has not. This routine is used by the "PAINT" statement so the following demonstrates the fault:

```
10 BASE(17)=&H1000
20 SCREEN 3
30 PSET(200,0)
40 DRAW"D180L100U180R100"
50 PAINT(150,90)
60 GOTO 60
```

Address... 17DCH

This is the Multicolour Mode version of the DOWNC standard routine, it is identical to the Graphics Mode version.

4. ROM BIOS

Address... 17E3H

This is the Multicolour Mode version of the TUPC standard routine. It is identical to the Graphics Mode version except that it has a bug as above, this time there should be an EX DE,HL instruction at address 17EBH.

If the Character Pattern Table base address is increased the routine will think it is within the table when it has actually exceeded the top edge of the screen. This may be demonstrated by removing the "R100" part of Line 40 in the previous program.

Address... 17F8H

This is the Multicolour Mode version of the UPC standard routine, it is identical to the Graphics Mode version.

Address... 1809H
Name..... NSETCX
Entry..... HL=Pixel fill count
Exit..... None
Modifies.. AF, BC, DE, HL, EI

Standard routine to set the colour of multiple pixels horizontally rightwards from the current pixel physical address. Although its function can be duplicated by the SETC and RIGHTC standard routines this would result in significantly slower operation. The supplied pixel count should be chosen so that the right-hand edge of the screen is not passed as this will produce anomalous behaviour. The current pixel physical address is unchanged by this routine.

In Graphics Mode CMASK is first examined to determine the number of pixels to the right within the current character cell. Assuming the fill count is large enough these are then set (186CH). The remaining fill count is divided by eight to determine the number of whole character cells. Successive bytes in the Character Pattern Table are then zeroed and the corresponding bytes in the Colour Table set from ATRBYT to fill these whole cells. The remaining fill count is then converted to a bit mask, using the seven byte table at 185DH, and these pixels are set (186CH).

In Multicolour Mode control transfers to a separate routine (18BBH).

Address... 186CH

This routine sets up to eight pixels within a cell to a specified colour in Graphics Mode. ATRBYT contains the colour code, register pair HL the address of the relevant byte in the Character Pattern Table and register A a bit mask, 11100000 for example, where every 1 specifies a bit to be set.

4. ROM BIOS

If ATRBYT matches the existing 1 pixel colour in the corresponding Colour Table byte then each specified bit is set to 1 in the Character Pattern Table byte. If ATRBYT matches the existing 0 pixel colour in the corresponding Colour Table byte then each specified bit is set to 0 in the Character Pattern Table byte.

If ATRBYT does not match either of the existing colours in the Colour Table Byte then normally each specified bit is set to 1 in the Character Pattern Table byte and the 1 pixel colour changed in the Colour Table byte. However if this would result in all bits being set to 1 in the Character Pattern Table byte then each specified bit is set to 0 and the 0 pixel colour changed in the Colour Table byte.

Address... 18BBH

This is the Multicolour Mode version of the NSETCX standard routine. The SETC and RIGHTC standard routines are called until the fill count is exhausted. Speed of operation is not so important in Multicolour Mode because of the lower screen resolution and the consequent reduction in the number of operations required.

Address... 18C7H
Name..... GTASPC
Entry..... None
Exit..... DE=ASPCT1, HL=ASPCT2
Modifies.. DE, HL

Standard routine to return the "CIRCLE" statement default aspect ratios.

Address... 18CFH
Name..... PNTINI
Entry..... A=Boundary colour (0 to 15)
Exit..... Flag C if illegal colour
Modifies.. AF

Standard routine to set the boundary colour for the "PAINT" statement. In Multicolour Mode the supplied colour code is placed in BDRATR. In Graphics Mode BDRATR is copied from ATRBYT as it is not possible to have separate paint and boundary colours.

Address... 18E4H
Name..... SCANR
Entry..... B=Fill switch, DE=Skip count
Exit..... DE=Skip remainder, HL=Pixel count
Modifies.. AF, BC, DE, HL, EI

Standard routine used by the "PAINT" statement handler to search rightwards from the current pixel physical address until a colour code equal to BDRATR is found or the edge of the

4. ROM BIOS

screen is reached. The terminating position becomes the current pixel physical address and the initial position is returned in CSAVEA and CSAVEM. The size of the traversed region is returned in register pair HL and FILNAM+1. The traversed region is normally filled in but this can be inhibited, in Graphics Mode only, by using an entry parameter of zero in register B. The skip count in register pair DE determines the maximum number of pixels of the required colour that may be ignored from the initial starting position. This facility is used by the "PAINT" statement handler to search for gaps in a horizontal boundary blocking its upward progress.

```
Address... 197AH
Name..... SCANL
Entry..... None
Exit..... HL=Pixel count
Modifies.. AF, BC, DE, HL, EI
```

Standard routine to search leftwards from the current pixel physical address until a colour code equal to BDRATR is found or the edge of the screen is reached. The terminating position becomes the current pixel physical address and the size of the traversed region is returned in register pair HL. The traversed region is always filled in.

```
Address... 19C7H
```

This routine is used by the SCANL and SCANR standard routines to check the current pixel's colour against the boundary colour in BDRATR.

```
Address... 19DDH
Name..... TAPOOF
Entry..... None
Exit..... None
Modifies.. EI
```

Standard routine to stop the cassette motor after data has been written to the cassette. After a delay of 550 ms, on MSX machines with one wait state, control drops into the TAPIOF standard routine.

```
Address... 19E9H
Name..... TAPIOF
Entry..... None
Exit..... None
Modifies.. EI
```

Standard routine to stop the cassette motor after data has been read from the cassette. The motor relay is opened via the PPI Mode Port. Note that interrupts, which must be disabled during cassette data transfers for timing reasons, are enabled as this routine terminates.

4. ROM BIOS

Address... 19F1H
Name..... TAPOON
Entry..... A=Header length switch
Exit..... Flag C if CTRL-STOP termination
Modifies.. AF, BC, HL, DI

Standard routine to turn the cassette motor on, wait 550 ms for the tape to come up to speed and then write a header to the cassette. A header is a burst of HI cycles written in front of every data block so the baud rate can be determined when the data is read back.

The length of the header is determined by the contents of register A: 00H=Short header, NZ=Long header. The BASIC cassette statements "SAVE", "CSAVE" and "BSAVE" all generate a long header at the start of the file, in front of the identification block, and thereafter use short headers between data blocks. The number of cycles in the header is also modified by the current baud rate so as to keep its duration constant:

1200 Baud	SHORT	...	3840 Cycles	...	1.5 Seconds
1200 Baud	LONG	...	15360 Cycles	...	6.1 Seconds
2400 Baud	SHORT	...	7936 Cycles	...	1.6 Seconds
2400 Baud	LONG	...	31744 Cycles	...	6.3 Seconds

After the motor has been turned on and the delay has expired the contents of HEADER are multiplied by two hundred and fifty-six and, if register A is non-zero, by a further factor of four to produce the cycle count. HI cycles are then generated (1A4DH) until the count is exhausted whereupon control transfers to the BREAKX standard routine. Because the CTRL-STOP key is only examined at termination it is impossible to break out part way through this routine.

Address... 1A19H
Name..... TAPOUT
Entry..... A=Data byte
Exit..... Flag C if CTRL-STOP termination
Modifies.. AF, B, HL

Standard routine to write a single byte of data to the cassette. The MSX ROM uses a software driven FSK (Frequency Shift Keyed) method for storing information on the cassette. At the 1200 baud rate this is identical to the Kansas City Standard used by the BBC for the distribution of BASICODE programs.

At 1200 baud each 0 bit is written as one complete 1200 Hz LO cycle and each 1 bit as two complete 2400 Hz HI cycles. The data rate is thus constant as 0 and 1 bits have the same duration. When the 2400 baud rate is selected the two frequencies change to 2400 Hz and 4800 Hz but the format is otherwise unchanged.

4. ROM BIOS

A byte of data is written with a 0 start bit (1A50H), eight data bits with the least significant bit first, and two 1 stop bits (1A40H). At the 1200 baud rate a single byte will have a nominal duration of $11 \times 833 \text{ } \mu\text{s} = 9.2 \text{ ms}$. After the stop bits have been written control transfers to the BREAKX standard routine to check the CTRL-STOP key. The byte 43H is shown below as it would be written to cassette:

1 = two "short" transitions (as STOP BITS)
 0 = one "long" transition (as START BIT)

Figure 39: Cassette Data Byte

It is important not to leave too long an interval between bytes when writing data as this will increase the error rate. An inter-byte gap of 80 μs , for example, produces a read failure rate of approximately twelve percent. If a substantial amount of processing is required between each byte then buffering should be used to lump data into headered blocks. The BASIC "SAVE" format is of this type.

Address... 1A39H

This routine writes a single LO cycle with a length of approximately 816 μs to the cassette. The length of each half of the cycle is taken from LOW and control transfers to the general cycle generator (1A50H).

Address... 1A40H

This routine writes two HI cycles to the cassette. The first cycle is generated (1A4DH) followed by a 17 μs delay and then the second cycle (1A4DH).

Address... 1A4DH

This routine writes a single HI cycle with a length of approximately 396 μs to the cassette. The length of each half of the cycle is taken from HIGH and control drops into the general cycle generator.

Address... 1A50H

This routine writes a single cycle to the cassette. The length of the cycle's first half is supplied in register L and its second half in register H. The first length is counted down and then the Cas Out bit set via the PPI Mode Port. The second length is counted down and the Cas Out bit reset.

4. ROM BIOS

On all MSX machines the Z80 runs at a clock frequency of 3.579545 MHz (280 ns) with one wait state during the M1 cycle. As this routine counts every 16T states each unit increment in the length count represents a period of 4.47 æs. There is also a fixed overhead of 20.7 æs associated with the routine whatever the length count.

Address... 1A63H
Name..... TAPION
Entry..... None
Exit..... Flag C if CTRL-STOP termination
Modifies.. AF, BC, DE, HL, DI

Standard routine to turn the cassette motor on, read the cassette until a header is found and then determine the baud rate. Successive cycles are read from the cassette and the length of each one measured (1B34H). When 1,111 cycles have been found with less than 35 æs variation in their lengths a header has been located.

The next 256 cycles are then read (1B34H) and averaged to determine the cassette HI cycle length. This figure is multiplied by 1.5 and placed in LOWLIM where it defines the minimum acceptable length of a 0 start bit. The HI cycle length is placed in WINWID and will be used to discriminate between LO and HI cycles.

Address... 1ABCH
Name..... TAPIN
Entry..... None
Exit..... A=Byte read, Flag C if CTRL-STOP or I/O error
Modifies.. AF, BC, DE, L

Standard routine to read a byte of data from the cassette. The cassette is first read continuously until a start bit is found. This is done by locating a negative transition, measuring the following cycle length (1B1FH) and comparing this to see if it is greater than LOWLIM.

Each of the eight data bits is then read by counting the number of transitions within a fixed period of time (1B03H). If zero or one transitions are found it is a 0 bit, if two or three are found it is a 1 bit. If more than three transitions are found the routine terminates with Flag C as this is presumed to be a hardware error of some sort. After the value of each bit has been determined a further one or two transitions are read (1B23H) to retain synchronization. With an odd transition count one more will be read, with an even transition count two more.

Address... 1B03H

This routine is used by the TAPIN standard routine to count the number of cassette transitions within a fixed period of

4. ROM BIOS

time. The window duration is contained in WINWID and is approximately 1.5 times the length of a HI cycle as shown below:

Figure 40: Cassette Window

The Cas Input bit is continuously sampled via PSG Register 14 and compared with the previous reading held in register E. Each time a change of state is found register C is incremented. The sampling rate is once every 17.3 μ s so the value in WINWID, which was determined by the TAPION standard routine with a count rate of 11.45 μ s, is effectively multiplied one and a half times.

Address... 1B1FH

This routine measures the time to the next cassette input transition. The Cassette Input bit is continuously sampled via PSG Register 14 until it changes from the state supplied in register E. The state flag is then inverted and the duration count returned in register C, each unit increment represents a period of 11.45 μ s.

Address... 1B34H

This routine measures the length of a complete cassette cycle from negative transition to negative transition. The Cassette Input bit is sampled via PSG Register 14 until it goes to zero. The transition flag in register E is set to zero and the time to the positive transition measured (1B23H). The time to the negative transition is then measured (1B25H) and the total returned in register C.

Address... 1B45H
 Name..... OUTDO
 Entry..... A=Character to output
 Exit..... None
 Modifies.. EI

Standard routine used by the BASIC Interpreter to output a character to the current device. The ISFLIO standard routine is

4. ROM BIOS

first used to check whether output is currently directed to an I/O buffer, if so control transfers to the sequential output driver (6C48H) via the CALBAS standard routine. If PRTFLG is zero control transfers to the CHPUT standard routine to output the character to the screen. Assuming the printer is active RAWPRT is checked. If this is non-zero the character is passed directly to the printer (1BABH), otherwise control drops into the OUTDLP standard routine.

Address... 1B63H
Name..... OUTDLP
Entry..... A=Character to output
Exit..... None
Modifies.. EI

Standard routine to output a character to the printer. If the character is a TAB code (09H) spaces are issued to the OUTDLP standard routine until LPTPOS is a multiple of eight (0, 8, 16 etc.). If the character is a CR code (0DH) LPTPOS is zeroed if it is any other control code LPTPOS is unaffected, if it is a displayable character LPTPOS is incremented.

If NTMSXP is zero, meaning an MSX-specific printer is connected, the character is passed directly to the printer (1BABH). Assuming a normal printer is connected the CNVCHR standard routine is used to check for graphic characters. If the character is a header code (01H) the routine terminates with no action. If it is a converted graphic character it is replaced by a space, all other characters are passed to the printer (1BACH).

Address... 1B97H

This twenty byte table is used by the keyboard decoder to find the correct routine for a given key number:

KEY NUMBER	TO	FUNCTION
AA		
00H to 2FH	0F83H	Rows 0 to 5
30H to 32H	0F10H	SHIFT, CTRL, GRAPH
33H	0F36H	CAP
34H	0F10H	CODE
35H to 39H	0FC3H	F1 to F5
3AH to 3BH	0F10H	ESC, TAB
3CH	0F46H	STOP
3DH to 40H	0F10H	BS, CR, SEL, SPACE
41H	0F06H	HOME
42H to 57H	0F10H	INS, DEL, CURSOR

Address... 1BABH

This routine is used by the OUTDLP standard routine to pass a character to the printer. It is sent via the LPTOUT standard routine, if this returns Flag C control transfers to the

4. ROM BIOS

"Device I/O error" generator (73B2H) via the CALBAS standard routine.

Address... 1BBFH

The following 2 KB contains the power-up character set. The first eight bytes contain the pattern for character code 00H, the second eight bytes the pattern for character code 01H and so on to character code FFH.

Address... 23BFH
Name..... PINLIN
Entry..... None
Exit..... HL=Start of text, Flag C if CTRL-STOP termination
Modifies.. AF, BC, DE, HL, EI

Standard routine used by the BASIC Interpreter Mainloop to collect a logical line of text from the console. Control transfers to the INLIN standard routine just after the point where the previous line has been cut (23E0H).

Address... 23CCH
Name..... QINLIN
Entry..... None
Exit..... HL=Start of text, Flag C if CTRL-STOP termination
Modifies.. AF, BC, DE, HL, EI

Standard routine used by the "INPUT" statement handler to collect a logical line of text from the console. The characters "? " are displayed via the OUTDO standard routine and control drops into the INLIN standard routine.

Address... 23D5H
Name..... INLIN
Entry..... None
Exit..... HL=Start of text, Flag C if CTRL-STOP termination
Modifies.. AF, BC, DE, HL, EI

Standard routine used by the "LINE INPUT" statement handler to collect a logical line of text from the console. Characters are read from the keyboard until either the CR or CTRL-STOP keys are pressed. The logical line is then read from the screen character by character and placed in the Workspace Area text buffer BUF.

The current screen coordinates are first taken from CSRX and CSRY and placed in FSTPOS. The screen row immediately above the current one then has its entry in LINTTB made non-zero (0C29H) to stop it extending logically into the current row.

Each keyboard character read via the CHGET standard routine is checked (0919H) against the editing key table at 2439H. Control then transfers to one of the editing routines or to the default key handler (23FFH) as appropriate. This process

4. ROM BIOS

continues until Flag C is returned by the CTRL-STOP or CR routines. Register pair HL is then set to point to the start of BUF and the routine terminates. Note that the carry, flag is cleared when Flag NZ is also returned to distinguish between a CR or protected CTRL-STOP termination and a normal CTRL-STOP termination.

Address... 23FFH

This routine processes all characters for the INLIN standard routine except the special editing keys. If the character is a TAB code (09H) spaces are issued (23FFH) until CSRX is a multiple of eight plus one (columns 1, 9, 17, 25, 33). If the character is a graphic header code (01H) it is simply echoed to the OUTDO standard routine. All other control codes smaller than 20H are echoed to the OUTDO standard routine after which INSFLG and CSTYLE are zeroed. For the displayable characters INSFLG is first checked and a space inserted (24F2H) if applicable before the character is echoed to the OUTDO standard routine.

Address... 2439H

This table contains the special editing keys recognized by the INLIN standard routine together with the relevant addresses:

CODE	TO	FUNCTION
AA		
08H	2561H	BS, backspace
12H	24E5H	INS, toggle insert mode
1BH	23FEH	ESC, no action
02H	260EH	CTRL-B, previous word
06H	25F8H	CTRL-F, next word
0EH	25D7H	CTRL-N, end of logical line
05H	25B9H	CTRL-E, clear to end of line
03H	24C5H	CTRL-STOP, terminate
0DH	245AH	CR, terminate
15H	25AEH	CTRL-U, clear line
7FH	2550H	DEL, delete character

Address... 245AH

This routine performs the CR operation for the INLIN standard routine. The starting coordinates of the logical line are found (266CH) and the cursor removed from the screen (0A2EH). Up to 254 characters are then read from the VDP VRAM (0BD8H) and placed in BUF. Any null codes (00H) are ignored, any characters smaller than 20H are replaced by a graphic header code (01H) and the character itself with 40H added. As the end of each physical row is reached LINTTB is checked (0C1DH) to see whether the logical line extends to the next physical row. Trailing spaces are then stripped from BUF and a zero byte added as an end of text marker. The cursor is

4. ROM BIOS

restored to the screen (09E1H) and its coordinates set to the last physical row of the logical line via the POSIT standard routine. A LF code is issued to the OUTDO standard routine, INSFLG is zeroed and the routine terminates with a CR code (0DH) in register A and Flag NZ,C. This CR code will be echoed to the screen by the INLIN standard routine mainloop just before it terminates.

Address... 24C5H

This routine performs the CTRL-STOP operation for the INLIN standard routine. The last physical row of the logical line is found by examining LINTTB (0C1DH), CSTYLE is zeroed, a zero byte is placed at the start of BUF and all music variables are cleared via the GICINI standard routine. TRPTBL is then examined (0454H) to see if an "ON STOP" statement is active, if so the cursor is reset (24AFH) and the routine terminates with Flag NZ,C. BASROM is then checked to see whether a protected ROM is running, if so the cursor is reset (24AFH) and the routine terminates with Flag NZ,C. Otherwise the cursor is reset (24B2H) and the routine terminates with Flag Z,C.

Address... 24E5H

This routine performs the INS operation for the INLIN standard routine. The current state of INSFLG is inverted and control terminates via the CSTYLE setting routine (242CH).

Address... 24F2H

This routine inserts a space character for the default key section of the INLIN standard routine. The cursor is removed (0A2EH) and the current cursor coordinates taken from CSRX and CSRY. The character at this position is read from the VDP VRAM (0BD8H) and replaced with a space (0BE6H). Successive characters are then copied one column position to the right until the end of the physical row is reached.

At this point LINTTB is examined (0C1DH) to determine whether the logical line is extended, if so the process continues on the next physical row. Otherwise the character taken from the last column position is examined, if this is a space the routine terminates by replacing the cursor (09E1H). Otherwise the physical row's entry in LINTTB is zeroed to indicate an extended logical line. The number of the next physical row is compared with the number of rows on the screen (0C32H). If the next row is the last one the screen is scrolled up (0A88H), otherwise a blank row is inserted (0AB7H) and the copying process continues.

Address... 2550H

This routine performs the DEL operation for the INLIN standard routine. If the current cursor position is at the

4. ROM BIOS

rightmost column and the logical line is not extended no action is taken other than to write a space to the VDP VRAM (2595H). Otherwise a RIGHT code (1CH) is issued to the OUTDO standard routine and control drops into the BS routine.

Address... 2561H

This routine performs the BS operation for the INLIN standard routine. The cursor is first removed (0A2EH) and the cursor column coordinate decremented unless it is at the leftmost position and the previous row is not extended. Characters are then read from the VDP VRAM (0BD8H) and written back one position to the left (0BE6H) until the end of the logical line is reached. At this point a space is written to the VDP VRAM (0BE6H) and the cursor character is restored (09E1H).

Address... 25AEH

This routine performs the CTRL-U operation for the INLIN standard routine. The cursor is removed (0A2EH) and the start of the logical line located (266CH) and placed in CSRX and CSRY. The entire logical line is then cleared (25BEH).

Address... 25B9H

This routine performs the CTRL-E operation for the INLIN standard routine. The cursor is removed (0A2EH) and the remainder of the physical row cleared (0AEEH). This process is repeated for successive physical rows until the end of the logical line is found in LINTBB (0C1DH). The cursor is then restored (09E1H), INSFLG zeroed and CSTLYE reset to a block cursor (242DH).

Address... 25D7H

This routine performs the CTRL-N operation for the INLIN standard routine. The cursor is removed (0A2EH) and the last physical row of the logical line found by examination of LINTTB (0C1DH). Starting at the rightmost column of this physical row characters are read from the VDP VRAM (0BD8H) until a non-space character is found. The cursor coordinates are then set one column to the right of this position (0A5BH) and the routine terminates by restoring the cursor (25CDH).

Address... 25F8H

This routine performs the CTRL-F operation for the INLIN standard routine. The cursor is removed (0A2EH) and moved successively right (2624H) until a non-alphanumeric character is found. The cursor is then moved successively right (2624H) until an alphanumeric character is found. The routine terminates by restoring the cursor (25CDH).

4. ROM BIOS

Address... 260EH

This routine performs the CTRL-B operation for the INLIN standard routine. The cursor is removed (0A2EH) and moved successively left (2634H) until an alphanumeric character is found. The cursor is then moved successively left (2634H) until a non-alphanumeric character is found and then moved one position right (0A5BH). The routine terminates by restoring the cursor (25CDH).

Address... 2624H

This routine moves the cursor one position right (0A5BH), loads register D with the rightmost column number, register E with the bottom row number and then tests for an alphanumeric character at the cursor position (263DH).

Address... 2634H

This routine moves the cursor one position left (0A4CH), loads register D with the leftmost column number and register E with the top row number. The current cursor coordinates are compared with these values and the routine terminates Flag Z if the cursor is at this position. Otherwise the character at this position is read from the VDP VRAM (0BD8H) and checked to see if it is alphanumeric. If so the routine terminates Flag NZ,C otherwise it terminates Flag NZ,NC.

The alphanumeric characters are the digits "0" to "9" and the letters "A" to "Z" and "a" to "z". Also included are the graphics characters 86H to 9FH and A6H to FFH, these were originally Japanese letters and should have been excluded during the conversion to the UK ROM.

Address... 266CH

This routine finds the start of a logical line and returns its screen coordinates in register pair HL. Each physical row above the current one is checked via the LINTTB table (0C1DH) until a non-extended row is found. The row immediately below this on the screen is the start of the logical line and its row number is placed in register L. This is then compared with FSTPOS, which contains the row number when the INLIN standard routine was first entered, to see if the cursor is still on the same line. If so the column coordinate in register H is set to its initial position from FSTPOS. Otherwise register H is set to the leftmost position to return the whole line.

Address...2680H, JP to power-up initialize routine (7C76H).

Address...2683H, JP to the SYNCHR standard routine (558CH).

Address...2686H, JP to the CHRGT standard routine (4666H).

Address...2689H, JP to the GETYPR standard routine (5597H).

5. ROM BASIC INTERPRETER

Microsoft BASIC has evolved over the years to its present position as the industry standard. It was originally written for the 8080 Microprocessor and even the MSX version is held in 8080 Assembly Language form. This process of continuous development means that there are less Z80-specific instructions than would be expected in a more modern program. It also means that numerous changes have been made and the result is a rather convoluted program. The structure of the Interpreter makes it unlikely that an application program will be able to use its many facilities. However most programs will need to cooperate with it to some extent so this chapter gives a detailed description of its operation.

There are four readily identifiable areas of importance within the Interpreter, the one most familiar to any user is the Mainloop (4134H). This collects numbered lines of text from the console and places them in order in the Program Text Area of memory until a direct statement is received.

The Runloop (4601H) is responsible for the execution of a program. It examines the first token of each program line and calls the appropriate routine to process the remainder of the statement. This continues until no more program text remains, control then returns to the Mainloop.

The analysis of numeric or string operands within a statement is performed by the Expression Evaluator (4C64H). Each expression is composed of factors, in turn analyzed by the Factor Evaluator (4DC7H), which are linked together by dyadic infix operators. As there are several types of operand, notably line numbers, which cannot form part of an expression in Microsoft BASIC the term "evaluated" is only used to refer to those that can. Otherwise a term such as "computed" will be used.

One point to note when examining the Interpreter in detail is that it contains a lot of trick code. The writers seem particularly fond of jumping into the middle of instructions to provide multiple entry points to a routine. As an example take the instruction:

```
3E D1      Normal: LD  A,0D1H
```

When encountered in the usual way this will of course load the accumulator with the value D1H. However if it is entered at "Normal" then it will be executed as a POP DE instruction. The Interpreter has many similarly obscure sections.

5. ROM BASIC INTERPRETER

Address... 268CH

This routine is used by the Expression Evaluator to subtract two double precision operands. The first operand is contained in DAC and the second in ARG, the result is returned in DAC. The second operand's mantissa sign is inverted and control drops into the addition routine.

Address... 269AH

This routine is used by the Expression Evaluator to add two double precision operands. The first operand is contained in DAC and the second in ARG, the result is returned in DAC. If the second operand is zero the routine terminates with no action, if the first operand is zero the second operand is copied to DAC (2F05H) and the routine terminates. The two exponents are compared, if they differ by more than 10^{15} the routine terminates with the larger operand as the result. Otherwise the difference between the two exponents is used to align the mantissae by shifting the smaller one rightwards (27A3H), for example:

$$\begin{aligned} 19.2100 &= .1921 \cdot 10^2 = .192100 \\ + .7436 &= .7436 \cdot 10^0 = .007436 \end{aligned}$$

If the two mantissa signs are equal the mantissae are then added (2759H), if they are different the mantissae are subtracted (276BH). The exponent of the result is simply the larger of the two original exponents. If an overflow was produced by addition the result mantissa is shifted right one digit (27DBH) and the exponent incremented. If leading zeroes were produced by subtraction the result mantissa is renormalized by shifting left (2797H). The guard byte is then examined and the result rounded up if the fifteenth digit is equal to or greater than five.

Address... 2759H

This routine adds the two double precision mantissae contained in DAC and ARG and returns the result in DAC. Addition commences at the least significant positions, DAC+7 and ARG+7, and proceeds two digits at a time for the seven bytes.

Address... 276BH

This routine subtracts the two double precision mantissae contained in DAC and ARG and returns the result in DAC. Subtraction commences at the guard bytes, DAC+8 and ARG+8, and proceeds two digits at a time for the eight bytes. If the result underflows it is corrected by subtracting it from zero and inverting the mantissa sign, for example:

$$0.17 - 0.85 = 0.32 = -0.68$$

5. ROM BASIC INTERPRETER

Address... 2797H

This routine shifts the double precision mantissa contained in DAC one digit left.

Address... 27A3H

This routine shifts a double precision mantissa right. The number of digits to shift is supplied in register A, the address of the mantissa's most significant byte is supplied in register pair HL. The digit count is first divided by two to separate the byte and digit counts. The required number of whole bytes are then shifted right and the most significant bytes zeroed. If an odd number of digits was specified the mantissa is then shifted a further one digit right.

Address... 27E6H

This routine is used by the Expression Evaluator to multiply two double precision operands. The first operand is contained in DAC and the second in ARG, the result is returned in DAC. If either operand is zero the routine terminates with a zero result (2E7DH). Otherwise the two exponents are added to produce the result exponent. If this is smaller than 10^{-63} the routine terminates with a zero result, if it is greater than 10^{63} an "Overflow error" is generated (4067H). The two mantissa signs are then processed to yield the sign of the result, if they are the same the result is positive, if they differ it is negative.

Even though the mantissae are in BCD format they are multiplied using the normal binary add and shift method. To accomplish this the first operand is successively multiplied by two (288AH) to produce the constants $X*80$, $X*40$, $X*20$, $X*10$, $X*8$, $X*4$, $X*2$, and X in the HOLD8 buffer. The second operand remains in ARG and DAC is zeroed to function as the product accumulator. Multiplication proceeds by taking successive pairs of digits from the second operand starting with the least significant pair. For each 1 bit in the digit pair the appropriate multiple of the first operand is added to the product. As an example the single multiplication $1823*96$ would produce:

$$1823*10010110=(1823*80)+(1823*10)+(1823*4)+(1823*2)$$

As each digit pair is completed the product is shifted two digits right. When all seven digit pairs have been processed the routine terminates by renormalizing and rounding up the product (26FAH).

The time required for a multiplication depends largely upon the number of 1 bits in the second operand. The worst case, when all the digits are sevens, can take up to 11 ms compared to the average of approximately 7 ms.

5. ROM BASIC INTERPRETER

Address... 288AH

This routine doubles a double precision mantissa three successive times to produce the products $X*2$, $X*4$ and $X*8$. The address of the mantissa's least significant byte is supplied in register pair DE. The products are stored at successively lower addresses commencing immediately below the operand.

Address... 289FH

This routine is used by the Expression Evaluator to divide two double precision operands. The first operand is contained in DAC and the second in ARG, the result is returned in DAC. If the first operand is zero the routine terminates with a zero result if the second operand is zero a "Division by zero" error is generated (4058H). Otherwise the two exponents are subtracted to produce the result exponent and the two mantissa signs processed to yield the sign of the result. If they are the same the result is positive, if they differ it is negative.

The mantissae are divided using the normal long division method. The second operand is repeatedly subtracted from the first until underflow to produce a single digit of the result. The second operand is then added back to restore the remainder (2761H), the digit is stored in HOLD and the first operand is shifted one digit left. When the first operand has been completely shifted out the result is copied from HOLD to DAC then renormalized and rounded up (2883H). The time required for a division reaches a maximum of approximately 25 ms when the first operand is composed largely of nines and the second operand of ones. This will require the greatest number of subtractions.

Address... 2993H

This routine is used by the Factor Evaluator to apply the "COS" function to a double precision operand contained in DAC. The operand is first multiplied (2C3BH) by $1/(2*PI)$ so that unity corresponds to a complete 360 degree cycle. The operand then has 0.25 (90 degrees) subtracted (2C32H), its mantissa sign is inverted (2E8DH) and control drops into the "SIN" routine.

Address... 29ACH

This routine is used by the Factor Evaluator to apply the "SIN" function to a double precision operand contained in DAC. The operand is first multiplied (2C3BH) by $1/(2*PI)$ so that unity corresponds to a complete 360 degree cycle. As the function is periodic only the fractional part of the operand is now required. This is extracted by pushing the operand (2CCCH) obtaining the integer part (30CFH) and copying it to ARG (2C4DH), popping the whole operand to DAC (2CE1H) and then subtracting the integer part (268CH).

5. ROM BASIC INTERPRETER

The first digit of the mantissa is then examined to determine the operand's quadrant. If it is in the first quadrant it is unchanged. If it is in the second quadrant it is subtracted from 0.5 (180 degrees) to reflect it about the Y axis. If it is in the third quadrant it is subtracted from 0.5 (180 degrees) to reflect it about the X axis. If it is in the fourth quadrant 1.0 (360 degrees) is subtracted to reflect it about both axes. The function is then computed by polynomial approximation (2C88H) using the list of coefficients at 2DEFH. These are the first eight terms in the Taylor series $X - (X^3/3!) + (X^5/5!) - (X^7/7!) \dots$ with the coefficients multiplied by successive factors of $2 \cdot \text{PI}$ to compensate for the initial scaling.

Address... 29FBH

This routine is used by the Factor Evaluator to apply the "TAN" function to a double precision operand contained in DAC. The function is computed using the trigonometric identity $\text{TAN}(X) = \text{SIN}(X)/\text{COS}(X)$.

Address... 2A14H

This routine is used by the Factor Evaluator to apply the "ATN" function to a double precision operand contained in DAC. The function is computed by polynomial approximation (2C88H) using the list of coefficients at 2E30H. These are the first eight terms in the Taylor series $X - (x^3/3) + (X^5/5) - (X^7/7) \dots$ with the coefficients modified slightly to telescope the series.

Address... 2A72H

This routine is used by the Factor Evaluator to apply the "LOG" function to a double precision operand contained in DAC. The function is computed by polynomial approximation using the list of coefficients at 2DA5H.

Address... 2AFFH

This routine is used by the Factor Evaluator to apply the "SQR" function to a double precision operand contained in DAC. The function is computed using the Newton-Raphson process, an equivalent BASIC program is:

```
10 INPUT"NUMBER";X
20 GUESS=10
30 FOR N=1 To 7
40 GUESS=(GUESS+X/GUESS)/2
50 NEXT N
60 PRINT GUESS
70 PRINT SQR(X)
```

The above program uses a fixed initial guess. While this is

5. ROM BASIC INTERPRETER

accurate over a limited range maximum accuracy will only be attained if the initial guess is near the root. The method used by the ROM is to halve the exponent, with rounding up, and then to divide the first two digits of the operand by four and increment the first digit.

Address... 2B4AH

This routine is used by the Factor Evaluator to apply the "EXP" function to a double precision operand contained in DAC. The operand is first multiplied by 0.4342944819, which is LOG(e) to Base 10, so that the problem becomes computing 10^X rather than e^X . This results in considerable simplification as the integer part can be dealt with easily. The function is then computed by polynomial approximation using the list of coefficients at 2D6BH.

Address... 2BDFH

This routine is used by the Factor Evaluator to apply the "RND" function to a double precision operand contained in DAC. If the operand is zero the current random number is copied to DAC from RNDX and the routine terminates. If the operand is negative it is copied to RNDX to set the current random number. The new random number is produced by copying RNDX to HOLD, the constant at 2CF9H to ARG, the constant at 2CF1H to DAC and then multiplying (282EH). The fourteen least significant digits of the double length product are copied to RNDX to form the mantissa of the new random number. The exponent byte in DAC is set to 10^0 to return a value in the range 0 to 1.

Address... 2C24H

This routine is used by the "NEW", "CLEAR" and "RUN" statement handlers to initialize RNDX with the constant at 2D01H.

Address... 2C2CH

This routine adds the constant whose address is supplied in register pair HL to the double precision operand contained in DAC.

Address... 2C32H

This routine subtracts the constant whose address is supplied in register pair HL from the double precision operand contained in DAC.

Address... 2C3BH

This routine multiplies the double precision operand contained in DAC by the constant whose address is supplied in register pair HL.

5. ROM BASIC INTERPRETER

Address... 2C41H

This routine divides the double precision operand contained in DAC by the constant whose address is supplied in register pair HL.

Address... 2C47H

This routine performs the relation operation on the double precision operand contained in DAC and the constant whose address is supplied in register pair HL.

Address... 2C4DH

This routine copies an eight byte double precision operand from DAC to ARG.

Address... 2C59H

This routine copies an eight byte double precision operand from ARG to DAC.

Address... 2C6FH

This routine exchanges the eight bytes in DAC with the eight bytes currently on the bottom of the Z80 stack.

Address... 2C80H

This routine inverts the mantissa sign of the operand contained in DAC (2E8DH). The same address is then pushed onto the stack to restore the sign when the caller terminates.

Address... 2C88H

This routine generates an odd series based on the double precision operand contained in DAC. The series is of the form:

$$X^{1*(Kn)} + X^{3*(Kn-1)} + X^{5*(Kn-2)} + X^{5*(Kn-3)} \dots$$

The address of the coefficient list is supplied in register pair HL. The first byte of the list contains the coefficient count, the double precision coefficients follow with K1 first and Kn last. The even series is generated (2C9AH) and multiplied (27E6H) by the original operand.

Address... 2C9AH

This routine generates an even series based on the double precision operand contained in DAC. The series is of the form:

$$X^{0*(Kn)} + X^{2*(Kn-1)} + X^{4*(Kn-2)} + X^{6*(Kn-3)} \dots$$

The address of the coefficient list is supplied in register

5. ROM BASIC INTERPRETER

pair HL. The first byte of the list contains the coefficient count, the double precision coefficients follow with K1 first and Kn last. The method used to compute the polynomial is known as Horner's method. It only requires one multiplication and one addition per term, the BASIC equivalent is:

```
10 X=X*X
20 PRODUCT=0
30 RESTORE 100
40 READ COUNT
50 FOR N=1 TO COUNT
60 READ K
70 PRODUCT= ( PRODUCT*X ) +K
80 NEXT N
90 END
100 DATA 8
110 DATA Kn-7
120 DATA Kn-6
130 DATA Kn-5
140 DATA Kn-4
150 DATA Kn-3
160 DATA Kn-2
170 DATA Kn-1
180 DATA Kn
```

The polynomial is processed from the final coefficient through to the first coefficient so that the partial product can be used to save unnecessary operations.

Address... 2CC7H

This routine pushes an eight byte double precision operand from ARG onto the Z80 stack.

Address... 2CCCH

This routine pushes an eight byte double precision operand from DAC onto the Z80 stack.

Address... 2CDCH

This routine pops an eight byte double precision operand from the Z80 stack into ARG.

Address... 2CE1H

This routine pops an eight byte double precision operand from the Z80 stack into DAC.

Address... 2CF1H

This table contains the double precision constants used by the math routines. The first three constants have zero in the exponent position as they are in a special intermediate form

5. ROM BASIC INTERPRETER

used by the random number generator.

Address... 2E71H

This routine returns the mantissa sign of a Floating Point operand contained in DAC. The exponent byte is tested and the result returned in register A and the flags:

Zero A=00H, Flag Z,NC
 Positive ... A=01H, Flag NZ,NC
 Negative ... A=FFH, Flag NZ,C

Address... 2E7DH

This routine simply zeroes the exponent byte in DAC.

Address... 2E82H

This routine is used by the Factor Evaluator to apply the "ABS" function to an operand contained in DAC. The operand's sign is first checked (2EAlH), if it is positive the routine simply terminates. The operand's type is then checked via the GETYPR standard routine. If it is a string a "Type mismatch" error is generated (406DH). If it is an integer it is negated

5. ROM BASIC INTERPRETER

(322BH). If it is a double precision or single precision operand the mantissa sign bit in DAC is inverted.

Address... 2E97H

This routine is used by the Factor Evaluator to apply the "SGN" function to an operand contained in DAC. The operand's sign is checked (2EA1H), extended into register pair HL and then placed in DAC as an integer:

```
Zero ..... 0000H
Positive ... 0001H
Negative ... FFFFH
```

Address... 2EA1H

This routine returns the sign of an operand contained in DAC. The operands type is first checked via the GETYPR standard routine. If it is a string a "Type mismatch" error is generated (406DH). If it is a single precision or double precision operand the mantissa sign is examined (2E71H). If it is an integer its value is taken from DAC+2 and translated into the flags shown at 2E71H.

Address... 2EB1H

This routine pushes a four byte single precision operand from DAC onto the Z80 stack.

Address... 2EC1H

This routine copies the contents of registers C, B, E and D to DAC.

Address... 2ECCH

This routine copies the contents of DAC to registers C, B, E and D.

Address... 2ED6H

This routine loads registers C, B, E and D from upwardly sequential locations starting at the address supplied in register pair HL.

Address... 2EDFH

This routine loads registers E, D, C and B from upwardly sequential locations starting at the address supplied in register pair HL.

Address... 2EE8H

This routine copies a single precision operand from DAC to

5. ROM BASIC INTERPRETER

the address supplied in register pair HL.

Address... 2EEFH

This routine copies any operand from the address supplied in register pair HL to ARG. The length of the operand is contained in VALTYP: 2=Integer, 3=String, 4=Single Precision, 8=Double Precision.

Address... 2F05H

This routine copies any operand from ARG to DAC. The length of the operand is contained in VALTYP: 2=Integer, 3=String, 4=Single Precision, 8=Double Precision.

Address... 2F0DH

This routine copies any operand from DAC to ARG. The length of the operand is contained in VALTYP: 2=Integer, 3=String, 4=Single Precision, 8=Double Precision.

Address... 2F21H

This routine is used by the Expression Evaluator to find the relation (<>=) between two single precision operands. The first operand is contained in registers C, B, E and D and the second in DAC. The result is returned in register A and the flags:

Operand 1=Operand 2 ... A=00H, Flag Z,NC
Operand 1<Operand 2 ... A=01H, Flag NZ,NC
Operand 1>Operand 2 ... A=FFH, Flag NZ,C

It should be noted that for relational operators the Expression Evaluator regards maximally negative numbers as small and maximally positive numbers as large.

Address... 2F4DH

This routine is used by the Expression Evaluator to find the relation (<>=) between two integer operands. The first operand is contained in register pair DE and the second in register pair HL. The results are as for the single precision version (2F21H).

Address... 2F83H

This routine is used by the Expression Evaluator to find the relation (<>=) between two double precision operands. The first operand is contained in DAC and the second in ARG. The results are as for the single precision version (2F21H).

Address... 2F8AH

This routine is used by the Factor Evaluator to apply the

5. ROM BASIC INTERPRETER

"CINT" function to an operand contained in DAC. The operand type is first checked via the GETYPR standard routine, if it is already integer the routine simply terminates. If it is a string a "Type mismatch" error is generated (406DH). If it is a single precision or double precision operand it is converted to a signed binary integer in register pair DE (305DH) and then placed in DAC as an integer. Out of range values result in an "Overflow" error (4067H).

Address... 2FA2H

This routine checks whether DAC contains the single precision operand -32768, if so it replaces it with the integer equivalent 8000H. This step is required during numeric input conversion (3299H) because of the asymmetric integer number range.

Address... 2FB2H

This routine is used by the Factor Evaluator to apply the "CSNG" function to an operand contained in DAC. The operand's type is first checked via the GETYPR standard routine, if it is already single precision the routine simply terminates. If it is a string a "Type mismatch" error is generated (406DH). If it is double precision VALTYP is changed (3053H) and the mantissa rounded up from the seventh digit (2741H). If the operand is an integer it is converted from binary to a maximum of five BCD digits by successive divisions using the constants 10000, 1000, 100, 10, 1. These are placed in DAC to form the single precision mantissa. The exponent is equal to the number of significant digits in the mantissa. For example if there are five the exponent would be 10^5 .

Address... 3030H

This table contains the five constants used by the "CSNG" routine: -10000, -1000, -100, -10, -1

Address... 303AH

This routine is used by the Factor Evaluator to apply the "CDBL" function to an operand contained in DAC. The operand's type is first checked via the GETYPR standard routine, if it is already double precision the routine simply terminates. If it is a string a "Type mismatch" error is generated (406DH). If it is an integer it is first converted to single precision (2FC8H), the eight least significant digits are then zeroed and VALTYP set to 8.

Address... 3058H

This routine checks that the current operand is a string type, if not a "Type mismatch" error is generated (406DH).

5. ROM BASIC INTERPRETER

Address... 305DH

This routine is used by the "CINT" routine (2F8AH) to convert a BCD single precision or double precision operand into a signed binary integer in register pair DE, it returns Flag C if an overflow has occurred. Successive digits are taken from the mantissa and added to the product starting with the most significant one. After each addition the product is multiplied by ten. The number of digits to process is determined by the exponent, for example five digits would be taken with an exponent of 10^5 . Finally the mantissa sign is checked and the product negated (3221H) if necessary.

Address... 30BEH

This routine is used by the Factor Evaluator to apply the "FIX" function to an operand contained in DAC. The operand's type is first checked via the GETYPR standard routine, if it is an integer the routine simply terminates. The mantissa sign is then checked (2E71H), if it is positive control transfers to the "INT" routine (30CFH). Otherwise the sign is inverted to positive, the "INT" function is performed (30CFH) and the sign restored to negative.

Address... 30CFH

This routine is used by the Factor Evaluator to apply the "INT" function to an operand contained in DAC. The operand's type is first checked via the GETYPR standard routine, if it is an integer the routine simply terminates. The number of fractional digits is determined by subtracting the exponent from the type's digit count, 6 for single precision, 14 for double precision.

If the mantissa sign is positive these fractional digits are simply zeroed. If the mantissa sign is negative each fractional digit is examined before it is zeroed. If all the digits were previously zero the routine simply terminates. Otherwise -1.0 is added to the operand by the single precision addition routine (324EH) or the double precision addition routine (269AH). It should be noted that an operand's type is not normally changed by the "CINT" function.

Address... 314AH

This routine multiplies the unsigned binary integers in register pairs BC and DE, the result is returned in register pair DE. The standard shift and add method is used, the product is successively multiplied by two and register pair BC added to it for every 1 bit in register pair DE. The routine is used by the Variable search routine (5EA4H) to compute an element's position within an Array, a "Subscript out of range" error is generated (601DH) if an overflow occurs.

5. ROM BASIC INTERPRETER

Address... 3167H

This routine is used by the Expression Evaluator to subtract two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. The second operand is negated (3221H) and control drops into the addition routine.

Address... 3172H

This routine is used by the Expression Evaluator to add two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. The signed binary operands are normally just added and placed in DAC. However, if an overflow has occurred both operands are converted to single precision (2FCBH) and control transfers to the single precision adder (324EH). An overflow has occurred when both operands are of the same sign and the result is of the opposite sign, for example:

$30000+15000=-20536$

Address... 3193H

This routine is used by the Expression Evaluator to multiply two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. The two operand signs are saved temporarily and both operands made positive (3215H). Multiplication proceeds using the standard binary shift and add method with register pair HL as the product accumulator, register pair BC containing the first operand and register pair DE the second. If the product exceeds 7FFFH at any time during multiplication both operands are converted to single precision (2FCBH) and control transfers to the single precision multiplier (325CH). Otherwise the initial signs are restored and, if they differ, the product negated before being placed in DAC as an integer (321DH).

Address... 31E6H

This routine is used by the Expression Evaluator to integer divide (\) two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. If the second operand is zero a "Division by zero" error is generated (4058H), otherwise the two operand signs are saved and both operands made positive (3215H). Division proceeds using the standard binary shift and subtract method with register pair HL containing the remainder, register pair BC the second operand and register pair DE the first operand and the product. When division is complete the initial signs are restored and, if they differ, the product is negated before being placed in DAC as an integer (321DH).

5. ROM BASIC INTERPRETER

Address... 3215H

This routine is used to make two signed binary integers, in register pairs HL and DE, positive. Both the initial operand signs are returned as a flag in bit 7 of register B: 0=Same, 1=Different. Each operand is then examined and, if it is negative, made positive by subtracting it from zero.

Address... 322BH

This routine is used by the "ABS" function to make a negative integer contained in DAC positive. The operand is taken from DAC, negated and then placed back in DAC (3221H). If the operand's value is 8000H it is converted to single precision (2FCCH) as there is no integer of value +32768.

Address... 323AH

This routine is used by the Expression Evaluator to "MOD" two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. The sign of the first operand is saved and the two operands divided (31E6H). As the remainder is returned doubled by the division process register pair DE is shifted one place right to restore it. The sign of the first operand is then restored and, if it is negative, the remainder is negated before being placed in DAC as an integer (321DH).

Address... 324EH

This routine is used by the Expression Evaluator to add two single precision operands. The first operand is contained in registers C, B, E, D and the second in DAC, the result is returned in DAC. The first operand is copied to ARG (3280H), the second operand is converted to double precision (3042H) and control transfers to the double precision adder (269AH).

Address... 3257H

This routine is used by the Expression Evaluator to subtract two single precision operands. The first operand is contained in registers C, B, E, D and the second in DAC, the result is returned in DAC. The second operand is negated (2E8DH) and control transfers to the single precision adder (324EH).

Address... 325CH

This routine is used by the Expression Evaluator to multiply two single precision operands. The first operand is contained in registers C, B, E, D and the second in DAC, the result is returned in DAC. The first operand is copied to ARG (3280H), the second operand is converted to double precision (3042H) and control transfers to the double precision multiplier (27E6H).

5. ROM BASIC INTERPRETER

Address... 3265H

This routine is used by the Expression Evaluator to divide two single precision operands. The first operand is contained in registers C, B, E, D and the second in DAC, the result is returned in DAC. The first and second operands are exchanged so that the first is in DAC and the second in the registers. The second operand is then copied to ARG (3280H), the first operand is converted to double precision (3042H) and control transfers to the double precision divider (289FH).

Address... 3280H

This routine copies the single precision operand contained in registers C, B, E and D to ARG and then zeroes the four least significant bytes.

Address... 3299H

This routine converts a number in textual form to one of the standard internal numeric types, it is used during tokenization and by the "VAL", "INPUT" and "READ" Statement handlers. On entry register pair HL points to the first character of the text string to be converted. On exit register pair HL points to the character following the string, the numeric operand is in DAC and the type code in VALTYP. Examples of the three types are:

```

UAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA;
 3      3      3 FFH 3 7FH 3      3      3      3      3
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAU
Integer +32767
    
```

```

UAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA;
 3 42H 3 17H 3 39H 3 04H 3      3      3      3      3
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAU
Single Precision .173904*10^2
    
```

```

UAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA;
 3 C2H 3 17H 3 39H 3 04H 3 62H 3 70H 3 93H 3 13H 3
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAU
Double Precision -.17390462709313*10^2
    
```

Figure 41: Numeric Types in DAC

An integer is a sixteen bit binary number in two's complement form, it is stored LSB first, MSB second at DAC+2. An integer can range from 8000H (-32768) to 7FFFH (+32767).

A floating point number consists of an exponent byte and a three or seven byte mantissa. The exponent is kept in signed binary form and can range from 01H (-63) through 40H (0) up to 7FH (+63), the special value of 00H is used for the number zero. These exponent values are for a normalized mantissa. The Interpreter presents exponent-form numbers to the user with a

5. ROM BASIC INTERPRETER

leading digit, this results in an asymmetric exponent range of E-64 to E+62. Bit 7 of the exponent byte holds the mantissa sign, 0 for positive and 1 for negative, the mantissa itself is kept in packed BCD form with two digits per byte. It should be noted that the Interpreter uses the contents of VALTYP to determine a number's type, not the format of the number itself.

Conversion starts by examining the first text character. If this is an "&" control transfers to the special radix conversion routine (4EB8H), if it is a leading sign character it is temporarily saved. Successive numeric characters are then taken and added to the integer product with appropriate multiplications by ten as each new digit is found. If the value of the product exceeds 32767, or a decimal point is found, the product is converted to single precision and any further characters placed directly in DAC. If a seventh digit is found the product is changed to double precision, if more than fourteen digits are found the excess digits are read but ignored.

Conversion ceases when a non-numeric character is found. If this a type definition character ("% ", "# " or "! ") the appropriate conversion routine is called and control transfers to the exit point (331EH). If it is an exponent prefix ("E", "e", "D" or "d") one of the conversion routines will also be used and then the following digits converted to a binary exponent in register E. At the exit point (331EH) the product's type is checked via the GETYPR standard routine. If it is single precision or double precision the exponent is calculated by first subtracting the fractional digit count, in register B, from the total digit count, in register D, to produce the leading digit count. This is then added to any explicitly stated exponent, in register E, and placed at DAC+0 as the exponent.

The leading sign character is restored and the product negated if required (2E86H), if the product is integer the routine then terminates. If the product is single precision control terminates by checking for the special value of -32768 (2FA2H). If the product is double precision control terminates by rounding up from the fifteenth digit (273CH).

Address... 340AH

This routine is used by the error handler to display the message " in " (6678H) followed by the line number supplied in register pair HL (3412H).

Address... 3412H

This routine displays the unsigned binary integer supplied in register pair HL. The operand is placed in DAC as an integer (2F99H), converted to text (3441H) and then displayed (6677H).

5. ROM BASIC INTERPRETER

Address... 3425H

This routine converts the numeric operand contained in DAC to textual form in FBUFR. The address of the first character of the resulting text is returned in register pair HL, the text is terminated by a zero byte. The operand is first converted to double precision (375FH). The BCD digits of the mantissa are then unpacked, converted to ASCII and placed in FBUFR (36B3H). The position of the decimal point is determined by the exponent, for example:

```
.999*10 ^ +2 = 99.9
.999*10 ^ +1 = 9.99
.999*10 ^ +0 = .999
.999*10 ^ -1 = .0999
```

If the exponent is outside the range 10^-1 to 10^14 the number is presented in exponential form. In this case the decimal point is placed after the first digit and the exponent is converted from binary and follows the mantissa.

An alternative entry point to the routine exists at 3426H for the "PRINT USING" statement handler. With this entry point the number of characters to prefix the decimal point is supplied in register B, the number of characters to point fix it in register C and a format byte in register A:

Figure 42: Format Byte

Operation in this mode is fairly similar to the normal mode but with the addition of extra facilities. Once the operand has been converted to double precision the exponential form will be assumed if bit 0 of the format byte is set. The mantissa is shifted to the right in DAC and rounded up to lose unwanted postfix digits (377BH). As the mantissa is converted to ASCII (36B3H) commas will be inserted at the appropriate points if bit 6 of the format byte is set. During post-conversion formatting (351CH) unused prefix positions will be filled with asterisks if bit 5 is set, a pound prefix may be added by setting bit 4. Bit 3 enables the "+" sign for positive numbers if set, otherwise a space is used. Bit 2 places any sign at the front if reset and at the back if set.

The entry point to the routine at 3441H is used to convert unsigned integers, notably line numbers, to their textual form. For example 9000H, when treated as a normal integer, would be converted to -28672. By using this entry point 36864 would be produced instead. The operand is converted by successive

5. ROM BASIC INTERPRETER

division with the factors 10000, 1000, 100, 10 and 1 and the resulting digits placed in FBUFFR (36DBH).

Address... 3710H

This table contains the five constants used by the numeric output routine: 10000, 1000, 100, 10, 1.

Address... 371AH

This routine is used by the "BIN\$" function to convert a numeric operand contained in DAC to textual form. Register B is loaded with the group size (1) and control transfers to the general conversion routine (3724H).

Address... 371EH

This routine is used by the "OCT\$" function to convert a numeric operand contained in DAC to textual form. Register B is loaded with the group size (3) and control transfers to the general conversion routine (3724H).

Address... 3722H

This routine is used by the "HEX\$" function to convert a numeric operand contained in DAC to textual form. Register B is loaded with the group size (4) and the operand converted to a binary integer in register pair HL (5439H). Successive groups of 1, 3 or 4 bits are shifted rightwards out of the operand, converted to ASCII digits and placed in FBUFFR. When the operand is all zeroes the routine terminates with the address of the first text character in register pair HL, the string is terminated with a zero byte.

Address... 3752H

This routine is used during numeric output to return an operand's digit count in register B and the address of its least significant byte in register pair HL. For single precision B=6 and HL=DAC+3, for double precision B=14 and HL=DAC+7.

Address... 375FH

This routine is used during numeric output to convert the numeric operand in DAC to double precision (303AH).

Address... 377BH

This routine is used during numeric output to shift the mantissa in DAC rightwards (27DBH), the inverse of the digit count is supplied in register A. The result is then rounded up from the fifteenth digit (2741H).

5. ROM BASIC INTERPRETER

Address... 37A2H

This routine is used during numeric output to return the inverse of the fractional digit count in a floating point operand. This is computed by subtracting the exponent from the operand's digit count (6 or 14).

Address... 37B4H

This routine is used during numeric output to locate the last non-zero digit of the mantissa contained in DAC. Its address is returned in register pair HL.

Address... 37C8H

This routine is used by the Expression Evaluator to exponentiate (^) two single precision operands. The first operand is contained in registers C, B, E, D and the second in DAC, the result is returned in DAC. The first operand is copied to ARG (3280H), pushed onto the stack (2CC7H) and exchanged with DAC (2C6FH). The second operand is then popped into ARG and control drops into the double precision exponentiation routine.

Address... 37D7H

This routine is used by the Expression Evaluator to exponentiate (^) two double precision operands. The first operand is contained in DAC and the second in ARG, the result is returned in DAC. The result is usually computed using:

$$X^P=EXP(P*LOG(X))$$

An alternative, much faster, method is possible if the power operand is an integer. This is tested for by extracting the integer part of the operand and comparing for equality with the original value (391AH). A positive result to this test means that the faster method can be used, this is described below.

Address... 383FH

This routine is used by the Expression Evaluator to exponentiate (^) two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. The routine operates by breaking the problem down into simple multiplications:

$$6^{13}=6^{1101}=(6^8)*(6^4)*(6^1)$$

As the power operand is in binary form a simple right shift is sufficient to determine whether a particular intermediate product needs to be included in the result. The intermediate products themselves are obtained by cumulative multiplication of the operand each time the computation loop is traversed. If

5. ROM BASIC INTERPRETER

the product overflows at any time it is converted to single precision. Upon completion the power operand is checked, if it is negative the product is reciprocated as $X^{-P}=1/X^P$.

Address... 390DH

This routine is used during exponentiation to multiply two integers (3193H), it returns Flag NZ if the result has overflowed to single precision.

Address... 391AH

This routine is used during exponentiation to check whether a double precision power operand consists only of an integer part, if so it returns Flag NC.

Address... 392EH

This table of addresses is used by the Interpreter Runloop to find the handler for a statement token. Although not part of the table the associated keywords are included below:

TO	STMT	TO	STMT	TO	STMT

Address... 3D26H

This twenty-one byte table is used by the Interpreter during program tokenization. It contains the ten single character keywords and their tokens:

+	...	F1H	*	...	F3H	^	...	F5H	'	...	E6H	=	...	EFH
-	...	F2H	/	...	F4H	\	...	FCH	>	...	EEH	<	...	F0H

5. ROM BASIC INTERPRETER

Address... 3D3BH

This table is used by the Expression Evaluator to determine the precedence level for a given infix operator, the higher the table value the greater the operator's precedence. Not included are the precedences for the relational operators (64H), the "NOT" operator (5AH) and the negation operator (7DH), these are defined directly by the Expression and Factor Evaluators.

79H ... +	46H ... OR
79H ... -	3CH ... XOR
7CH ... *	32H ... EQV
7CH ... /	28H ... IMP
7FH ... ^	7AH ... MOD
50H ... AND	7BH ... \

Address... 3D47H

This table is used to convert the result of a user defined function to the same type as the Variable used in the function definition. It contains the addresses of the type conversion routines:

303AH ... CDBL
0000H ... Not used
2F8AH ... CINT
3058H ... Check string type
2FB2H ... CSNG

Address... 3D51H

This table of addresses is used by the Expression Evaluator to find the handler for a particular infix math operator when both operands are double precision:

269AH ... +
268CH ... -
27E6H ... *
289FH ... /
37D7H ... ^
2F83H ... Relation

Address... 3D5DH

This table of addresses is used by the Expression Evaluator to find the handler for a particular infix math operator when both operands are single precision:

324EH ... +
3257H ... -
325CH ... *
3267H ... /
37C8H ... ^
2F21H ... Relation

5. ROM BASIC INTERPRETER

Address... 3D69H

This table of addresses is used by the Expression Evaluator to find the handler for a particular infix math operator when both operands are integer:

```
3172H ... +
3167H ... -
3193H ... *
4DB8H ... /
383FH ... ^
2F4DH ... Relation
```

Address... 3D75H

This table contains the Interpreter error messages, each one is stored in plain text with a zero byte terminator. The associated error codes are shown below for reference only, they do not form part of the table:

01 NEXT without FOR	19 Device I/O error
02 Syntax error	20 Verify error
03 RETURN without GOSUB	21 No RESUME
04 Out of DATA	22 RESUME without error
05 Illegal function call	23 Unprintable error
06 Overflow	24 Missing operand
07 Out of memory	25 Line buffer overflow
08 Undefined line number	50 FIELD overflow
09 Subscript out of range	51 Internal error
10 Redimensioned array	52 Bad file number
11 Division by zero	53 File not found
12 Illegal direct	54 File already open
13 Type mismatch	55 Input past end
14 Out of string space	56 Bad file name
15 String too long	57 Direct statement in file
16 String formula too complex	58 Sequential I/O only
17 Can't CONTINUE	59 File not OPEN
18 Undefined user function	

Address... 3FD2H

This is the plain text message " in " terminated by a zero byte.

Address... 3FD7H

This is the plain text message "Ok", CR, LF terminated by a zero byte.

Address... 3FDCH

This is the plain text message "Break" terminated by a zero byte.

5. ROM BASIC INTERPRETER

Address... 3FE2H

This routine searches the Z80 stack for the "FOR" loop parameter block whose loop Variable address is supplied in register pair DE. The search is started four bytes above the current Z80 SP to allow for the caller's return address and the Runloop return address. If no "FOR" token (82H) exists the routine terminates Flag NZ, if one is found the loop Variable address is taken from the parameter block and checked. The routine terminates Flag Z upon a successful match with register pair HL pointing to the type byte of the parameter block. Otherwise the search moves up twenty-two bytes to the start of the next parameter block.

Address... 4001H

This routine is used by the Factor Evaluator to apply the "INP" function to an operand contained in DAC. The port number is checked (5439H), the port read and the result placed in DAC as an integer (4FCFH).

Address... 400BH

This routine first evaluates an operand in the range -32768 to +65535 (542FH) and places it in register pair BC. After checking for a comma, via the SYNCHR standard routine, it evaluates a second operand in the range 0 to 255 (521CH) and places this in register A.

Address... 4016H

This is the "OUT" statement handler. The port number and data byte are evaluated (400BH) and the data byte written to the relevant Z80 port.

Address... 401CH

This is the "WAIT" statement handler. The port number and "AND" operands are first evaluated (400BH) followed by the optional "XOR" operand (521CH). The port is then repeatedly read and the operands applied, XOR then AND, until a non-zero result is obtained. Contrary to the information given in some MSX manuals the loop can be broken by the CTRL-STOP key as the CKCNTC standard routine is called from inside it.

Address... 4039H

This routine is used by the Runloop when it encounters the end of the program text while in program mode. ONEFLAG is checked to see whether it still contains an active error code. If so a "No RESUME" error is generated, otherwise program termination continues normally (6401H). The idea behind this routine is to catch any "ON ERROR" handlers without a "RESUME" statement at the end.

5. ROM BASIC INTERPRETER

Address... 411FH

This is the re-entry point to the Interpreter Mainloop for a terminating program. The screen is forced to text mode via the TOTEXT standard routine, the printer is cleared (7304H) and I/O buffer 0 closed (6D7BH). A CR,LF is then issued to the screen (7323H), the message "OK" is displayed (6678H) and control drops into the Mainloop.

Address... 4134H

This is the Interpreter Mainloop. CURLIN is first set to FFFFH to indicate direct mode and AUTFLG checked to see if "AUTO" mode is on. If so the next line number is taken from AUTLIN and displayed (3412H). The Program Text Area is then searched to see if this line already exists (4295H) and either an asterisk or space displayed accordingly.

The ISFLIO standard routine is then used to determine whether a "LOAD" statement is active. If so the program line is collected from the cassette (7374H), otherwise it is taken from the console via the PINLIN standard routine. If the line is empty or the CTRL-STOP key has been pressed control transfers back to the start of the Mainloop (4134H) with no further action. If the line commences with a line number this is converted to an unsigned integer in register pair DE (4769H). The line is then converted to tokenized form and placed in KBUF (42B2H). If no line number was found at the start of the line control then transfers to the Runloop (6D48H) to execute the statement.

Assuming the line commences with a line number it is tested to see if it is otherwise empty and the result temporarily saved. The line number is copied to DOT and AUTLIN increased by the contents of AUTINC, if AUTLIN now exceeds 65530 the "AUTO" mode is turned off. The Program Text Area is then searched (4295H) to find a matching line number or, failing this, the position of the next highest line number. If no matching line number is found and the line is empty and "AUTO" mode is off an "Undefined line number" error is generated (481CH). If a matching line number is found and the line is empty and "AUTO" mode is on the Mainloop simply skips to the next statement (4237H).

Otherwise any pointers in the Program Text Area are converted back to line numbers (54EAH) and any existing program line deleted (5405H). Assuming the new program line is non-empty the Program Text Area is opened up by the required amount (6250H) and the tokenized program line copied from KBUF.

The Program Text Area links are then recalculated (4257H), the Variable Storage Areas are cleared (629AH) and control transfers back to the start of the Mainloop.

5. ROM BASIC INTERPRETER

Address... 4253H

This routine recalculates the Program Text Area links after a program modification. The first two bytes of each program line contain the starting address of the following line, this is called the link. Although the link increases the amount of storage required per program line it greatly reduces the time required by the Interpreter to locate a given line.

An example of a typical program line is shown below, in this case the line "10 PRINT 9" situated at the start of the Program Text Area (8001H):

```
ÚAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA;
 ³ 09H 80H ³ 0AH 00H ³ 91H ³ 20H ³ 1AH ³ 00H ³
ÀAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAÙ
```

Figure 43: Program Line

In the above example the link is stored in Z80 word order (LSB,MSB) and is immediately followed by the binary line number, also in word order. The statement itself is composed of a "PRINT" token (91H), a single space, the number nine and the end of line character (00H). Further details of the storage format can be found in the tokenizing routine (42B2H).

Each link is recalculated simply by scanning through the line until the end of line character is found. The process is complete when the end of the Program Storage Area, marked by the special link of 0000H, is reached.

Address... 4279H

This routine is used by the "LIST" statement handler to collect up to two line number operands from the program text. If the first line number is present it is converted to an unsigned integer in register pair DE (475FH), if not a default value of 0000H is returned. If the second line number is present it must be preceded by a "-" token (F2H) and is returned on the Z80 stack, if not a default value of 65530 is returned. Control then drops into the program text search routine to find the first referenced program line.

Address... 4295H

This routine searches the Program Text Area for the program line whose line number is supplied in register pair DE. Starting at the address contained in TXTTAB each program line is examined for a match. If an equal line number is found the routine terminates with Flag Z,C and register pair BC pointing to the start of the program line. If a higher line number is found the routine terminates Flag NZ,NC and if the end link is reached the routine terminates Flag Z,NC.

5. ROM BASIC INTERPRETER

Address... 42B2H

This routine is used by the Interpreter Mainloop to tokenize a line of text. On entry register pair HL points to the first text character in BUF. On exit the tokenized line is in KBUF, register pair BC holds its length and register pair HL points to its start.

Except after opening quotes or after the "REM", "CALL" or "DATA" keywords any string of characters matching a keyword is replaced by that keyword's token. Lower case alphabetic characters are changed to upper case for keyword comparison. The character "?" is replaced by the "PRINT" token (91H) and the character "'" by ":" (3AH), "REM" token (8FH), "" token (E6H). The "ELSE" token (A1H) is preceded by a statement separator (3AH). Any other miscellaneous characters in the text are copied without alteration except that lower case alphabetic characters are converted to upper case. Those tokens smaller than 80H, the function tokens, cannot be stored directly in KBUF as they will conflict with ordinary text. Instead the sequence FFH, token+80H is used.

Numeric constants are first converted into one of the standard types in DAC (3299H). They are then stored in one of several ways depending upon their type and magnitude, the general idea being to minimize memory usage:

0BH LSB MSB	Octal number
0CH LSB MSB	Hex number
11H to 1AH	Integer 0 to 9
0FH LSB	Integer 10 to 255
1CH LSB MSB	Integer 256 to 32767
1DH EE DD DD DD	Single Precision
1FH EE DD DD DD DD DD DD	Double Precision

There is no specific token for binary numbers, these are left as character strings. This would appear to be a legacy from earlier versions of Microsoft BASIC. Any sign prefixing a number is regarded as an operator and is stored as a separate token, negative numbers are not produced during tokenization. As double precision numbers occupy so much space a line containing too many, for example PRINT 1#,1#,1# etc. may cause KBUF to fill up. If this happens a "Line buffer overflow" error is generated.

Any number following one of the keyword tokens in the table at 43B5H is considered to be a line number operand and is stored with a different token:

0DH LSB MSB	Pointer
0EH LSB MSB	Line number

During tokenization only the normal type (0EH) is generated, when a program actually runs these line number operands are converted to the address pointer type (0DH).

5. ROM BASIC INTERPRETER

Address... 43B5H

This table of tokens is used during tokenization to check for the keywords which take line number operands. The keywords themselves are listed below:

RESTORE	RUN
AUTO	LIST
RENUM	LLIST
DELETE	GOTO
RESUME	RETURN
ERL	THEN
ELSE	GOSUB

Address... 4524H

This is the "FOR" statement handler. The loop Variable is first located and assigned its initial value by the "LET" handler (4880H), the address of the loop Variable is returned in register pair DE. The end of the statement is found (485BH) and its address placed in ENDFOR. The Z80 stack is then searched (3FE6H) for any parameter blocks using the same loop Variable. For each one found the current ENDFOR address is compared with that of the parameter block, if there is a match that section of the stack is discarded. This is done in case there are any incomplete loops as a result of a "GOTO" back to the "FOR" statement from inside the loop.

The termination operand and optional "STEP" operand are then evaluated and converted to the same type as the loop Variable. After checking that stack space is available (625EH) a twenty-five byte parameter block is pushed onto the Z80 stack. This is made up of the following:

2 bytes	... ENDFOR address
2 bytes	... Current line number
8 bytes	... Loop termination value
8 bytes	... STEP value
1 byte	... Loop type
1 byte	... STEP direction
2 bytes	... Address of loop Variable
1 byte	... FOR token (82H)

The parameter block remains on the stack for use by the "NEXT" statement handler until termination is reached, it is then discarded. The size of the block remains constant even though, for integer and single precision loop Variables, the full eight bytes are not required for the termination and STEP values. In these cases the least significant bytes are packed out with garbage.

It should be noted that the type of arithmetic operation performed by the "NEXT" statement handler, and hence the loop execution speed, depends entirely upon the loop Variable type

5. ROM BASIC INTERPRETER

and not the operand types. For the fastest program execution integer type Variables, N% for example, should be used.

Address... 4601H

This is the Runloop, each statement handler returns here upon completion so the Interpreter can proceed to the next statement. The current Z80 SP is copied to SAVSTK for error recovery purposes and the CTRL-STOP key checked via the ISCNTC standard routine. Any pending interrupts are processed (6389H) and the current program text position, held in register pair HL throughout the Interpreter, is copied to SAVTXT.

The current program character is then examined, if this is a statement separator (3AH) control transfers immediately to the execution point (4640H). If it is anything else but an end of line character (00H) a "Syntax error" is generated (4055H) as there is spurious text at the end of the statement. Register pair HL is advanced to the first character of the new program line and the link examined, if this is zero the program is terminated (4039H). Otherwise the line number is taken from the new line and placed in CURLIN. If TRCFLG is non-zero the line number is displayed (3412H) enclosed by square brackets, control then drops into the execution point.

Address... 4640H

This is the Runloop execution point. A return to the start of the Runloop (4601H) is pushed onto the Z80 stack and the first character taken from the new statement via the CHRGT standard routine. If it is an underline character (5FH) control transfers to the "CALL" statement handler (55A7H). If it is smaller than 81H, the smallest statement token, control transfers to the "LET" handler (4880H). If it is larger than D8H, the largest statement token, it is checked to see if it is one of the function tokens allowed as a statement (51ADH). Otherwise the handler address is taken from the table at 392EH and pushed onto the stack. Control then drops into the CHRGT standard routine to fetch the next program character before control transfers to the statement handler.

Address... 4666H

Name..... CHRGT

Entry..... HL points to current program character

Exit..... A=Next program character

Modifies.. AF, HL

Standard routine to fetch the next character from the program text. Register pair HL is incremented and the character placed in register A. If it is a space, TAB code (09H) or LF code (0AH) it is skipped over. If it is a statement separator (3AH) or end of line character (00H) the routine terminates with Flag Z,NC. If it is a digit from "0" to "9" the routine terminates with Flag NZ,C. If it is any other character apart

5. ROM BASIC INTERPRETER

from the numeric prefix tokens the routine terminates Flag NZ,NC. If the character is one of the numeric prefix tokens then it is placed in CONSAV and the operand copied to CONLO. The type code is placed in CONTYP and the address of the trailing program character in CONTXT.

Address... 46E8H

This routine is used by the Factor Evaluator and during detokenization to recover a numeric operand when one of the prefix tokens is returned by the CHRGT standard routine. The prefix token is first taken from CONSAV, if it is anything but a line number or pointer token the operand is copied from CONLO to DAC and the type code copied from CONTYP to VALTYP. If it is a line number it is converted to single precision and placed in DAC (3236H). If it is a pointer the original line number is recovered from the referenced program line, converted to single precision and placed in DAC (3236H).

Address... 4718H

This is the "DEFSTR" statement handler. Register E is loaded with the string type code (03H) and control drops into the general type definition routine.

Address... 471BH

This is the "DEFINT" statement handler. Register E is loaded with the integer type code (02H) and control drops into the general type definition routine.

Address... 471EH

This is the "DEFSNG" statement handler. Register E is loaded with the single precision type code (04H) and control drops into the general type definition routine.

Address... 4721H

This is the "DEFDBL" statement handler. Register E is loaded with the double precision type code (08H) and the first range definition character checked (64A7H). If this is not upper case alphabetic a "Syntax error" is generated (4055H). If a "-" token (F2H) follows the second range definition character is taken and checked (64A7H), the difference between the two determines the number of entries in DEFTBL that are filled with the type code.

Address... 4755H

This routine evaluates an operand and converts it to an integer in register pair DE (520FH). If the operand is negative an "Illegal function call" error is generated.

5. ROM BASIC INTERPRETER

Address... 475FH

This routine is used by the statement handlers shown in the table at 43B5H to collect a single line number operand from the program text and convert it to an unsigned integer in register pair DE. If the first character in the text is a "." (2EH) the routine terminates with the contents of DOT. If it is one of the line number tokens (0DH or 0EH) the routine terminates with the contents of CONLO. Otherwise successive digits are taken and added to the product, with appropriate multiplications by ten, until a non-numeric character is found.

Address... 479EH

This is the "RUN" statement handler. If no line number operand is present in the program text the system is cleared (629AH) and control returns to the Runloop with register pair HL pointing to the start of the Program Storage Area. If a line number operand is present the system is cleared (62A1H) and control transfers to the "GOTO" statement handler (47E7H). Otherwise a following filename is assumed, for example RUN "CAS:FILE", and control transfers to the "LOAD" statement handler (6B5BH);

Address... 47B2H

This is the "GOSUB" statement handler. After checking that stack space is available (625EH) the line number operand is collected and placed in register pair DE (4769H). The seven byte parameter block is then pushed onto the stack and control transfers to the "GOTO" handler (47EBH). The parameter block is made up of the following:

- 2 bytes ... End of statement address
- 2 bytes ... Current line number
- 2 bytes ... 0000H
- 1 byte ... GOSUB token (8DH)

The parameter block remains on the stack until a "RETURN" statement is executed. It is then used to determine the original program text position after which it is discarded.

Address... 47CFH

This routine is used by the Runloop interrupt processor (6389H) to create a "GOSUB" type parameter block on the Z80 stack. An interrupt block is identical to a normal block except that the two zero bytes shown above are replaced by the address of the device's entry in TRPTBL. This address will be used by the "RETURN" statement handler to update the device's interrupt status once a subroutine has terminated. After pushing the parameter block control transfers to the Runloop to execute the program line whose address is supplied in register pair DE.

5. ROM BASIC INTERPRETER

Address... 47E8H

This is the "GOTO" statement handler. The line number operand is collected (4769H) and placed in register pair HL. If it is a pointer control transfers immediately to the Runloop to begin execution at the new program text position. Otherwise the line number is compared with the current line number to determine the starting position for the program text search. If it is greater the search starts from the end of this line (4298H), if it is smaller it starts from the beginning of the Program Text Area (4295H). If the referenced line cannot be found an "Undefined line number" error is generated (481CH). Otherwise the line number operand is replaced by the referenced program line's address and its token changed to the pointer type (5583H). Control then transfers to the Runloop to execute the referenced program line.

Address... 481CH

This is the "Undefined line number" error generator.

Address... 4821H

This is the "RETURN" statement handler. A dummy loop Variable address is placed in register pair DE and the Z80 stack searched (3FE2H) to find the first parameter block not belonging to a "FOR" loop, this section of stack is then discarded. If no "GOSUB" token (8DH) is found at this point a "RETURN without GOSUB" error is generated.

The next two bytes are then taken from the block, if they are non-zero the block was generated by an interrupt and the temporary "STOP" condition is removed (633EH). The program text is then examined, if anything follows the "RETURN" token itself it is assumed to be a line number operand and control transfers to the "GOTO" handler (47E8H). Otherwise the old line number and program text address are taken from the block and control returns to the Runloop.

Address... 485BH

This is the "DATA" statement handler. The program text is skipped over until a statement separator (3AH) or end of line character (00H) is found. This routine is also the "REM" and "ELSE" statement handler via the entry point at 485DH, in this case only the end of line character acts as a terminator.

Address... 4880H

This is the "LET" statement handler. The Variable is first located (5EA4H), its address saved in TEMP and the operand evaluated (4C64H). If necessary the operand's type is then changed to match that of the Variable (517AH). Assuming the operand is one of the three numeric types it is simply copied

5. ROM BASIC INTERPRETER

from DAC to the Variable in the Variable Storage Area (2EF3H). If the operand is a string type the address of the string body is taken from the descriptor and checked. If it is in KBUF, as would be the case for an explicit string in a direct statement, the body is first copied to the String Storage Area and a new descriptor created (6611H). The descriptor is then freed from TEMPST (67EEH) and copied to the Variable in the Variable Storage Area (2EF3H).

Address... 48E4H

This is the "ON ERROR", "ON DEVICE GOSUB" and "ON EXPRESSION" statement handler. If the next program text character is not an "ERROR" token (A6H) control transfers to the "ON DEVICE GOSUB" and "ON EXPRESSION" handler (490DH). The program text is checked to ensure that a "GOTO" token (89H) follows and then the line number operand collected (4769H). The program text is searched to obtain the address of the referenced line (4293H) and this is placed in ONELIN. If the line number operand is non-zero the routine then terminates. If the line number operand is zero ONEFLG is checked to see if an error situation already exists (implying that the statement is inside a BASIC error recovery routine). If so control transfers to the error handler (4096H) to force an immediate error, otherwise the routine terminates normally.

Address... 490DH

This is the "ON DEVICE GOSUB" and "ON EXPRESSION" statement handler. If the next program text character is not a device token (7810H) control transfers to the "ON EXPRESSION" handler (4943H). After checking the program text for a "GOSUB" token (8DH) each of the line number operands required for a particular device is collected in turn (4769H). Assuming a given line number operand is non-zero the program text is searched to find the address of the referenced line (4293H) and this is placed in the device's entry in TRPTBL (785CH). The routine terminates when no more line number operands are found.

Address... 4943H

This is the "ON EXPRESSION" statement handler. The operand is evaluated (521CH) and the following "GOSUB" token (8DH) or "GOTO" token (89H) placed in register A. The operand is then used to count along the program text until register pair HL points to the required line number operand. Control then transfers back to the Runloop execution point (4646H) to decode the "GOSUB" or "GOTO" token.

Address... 495DH

This is the "RESUME" statement handler. ONEFLG is first checked to make sure that an error condition already exists, if not a "RESUME without error" is generated (4064H). If a non-

5. ROM BASIC INTERPRETER

zero line number operand follows control transfers to the "GOTO" handler (47EBH). If a "NEXT" token (83H) follows the position of the error is restored from ERRTXT and ERRLIN, the start of the next statement is found (485BH) and the routine terminates. If there is no line number operand or if it is zero the position of the error is found from ERRTXT and ERRLIN and the routine terminates.

Address... 49AAH

This is the "ERROR" statement handler. The operand is evaluated and placed in register E (521CH). If it is zero an "Illegal function call" error is generated (475AH), otherwise control transfers to the error handler (406FH).

Address... 49B5H

This is the "AUTO" Statement handler. The optional start and increment line number operands, both with a default value of ten, are collected (475FH) and placed in AUTLIN and AUTINC. After making AUTFLG non-zero the Runloop return is destroyed and control transfers directly to the Mainloop (4134H).

Address... 49E5H

This is the "IF" statement handler. The operand is evaluated (4C64H) and, after checking for a "GOTO" token (89H) or "THEN" token (DAH), its sign is tested (2EA1H). If the operand is non-zero (true) the following text is executed either by an immediate transfer to the Runloop (4646H) or, for a line number operand, the "GOTO" handler (47E8H). If the operand is zero (false) the statement text is scanned (485BH) until an "ELSE" token (A1H) is found not balanced by an "IF" token (8BH) and execution re-commences.

Address... 4A1DH

This is the "LPRINT" statement handler. PRTFLG is set to 01H, to direct output to the printer, and control transfers to the "PRINT" handler (4A29H).

Address... 4A24H

This is the "PRINT" statement handler. The program text is first checked for a trailing buffer number and, if necessary, PTRFIL set to direct output to the required I/O buffer (6D57H). If no more program text exists a CR,LF is issued (7328H) and the routine terminates (4AFFH). Otherwise successive characters are taken from the program text and analyzed. If a "USING" token (E4H) is found control transfers to the "PRINT USING" handler (60B1H). If a ";" character is found control just transfers back to the start to fetch the next item (4A2EH). If a comma is found sufficient spaces are issued to bring the current print position, from TTYPOS, LPTPOS or an I/O buffer

5. ROM BASIC INTERPRETER

FCB, to an integral multiple of fourteen. If output is directed to the screen and the print position is equal to or greater than the contents of CLMLST or if output is directed to the printer and it is equal to or greater than 238 then a CR,LF is issued instead (7328H). If a "SPC(" token (DFH) is found the operand is evaluated (521BH) and the required number of spaces are output. If a "TAB(" token (DBH) is found the operand is evaluated (521BH) and sufficient spaces issued to bring the current print position, from TTYPOS, LPTPOS or an I/O buffer FCB, to the required point.

If none of these characters is found the program text contains a data item which is then evaluated (4C64H). If the operand is a string it is simply displayed (667BH). If it is numeric it is first converted to text in FBUFFR (3425H) and a string descriptor created (6635H). If output is directed to an I/O buffer the resulting string is then displayed (667BH). If output is directed to the screen or printer the current print position, from TTYPOS or LPTPOS, is compared with the line length and a CR,LF issued (7328H) if the output will not fit on the line. The maximum line length is 255 for the printer and is taken from LINLEN for the screen. Once the string has been displayed control transfers back to the start of the handler.

Address... 4AFFH

This routine zeroes PRTFLG and PTRFIL to return the Interpreter's output to the screen.

Address... 4B0EH

This is the "LINE INPUT", "LINE INPUT#" and "LINE" statement handler. If the following program text character is anything other than an "INPUT" token (85H) control transfers to the "LINE" statement handler (58A7H). If the following program text character is a "#" (23H) control transfers to the "LINE INPUT#" statement handler (6D8FH).

Any following prompt string is evaluated and displayed (4B7BH) and the Variable located (5EA4H) and checked to ensure that it is a string type (3058H). The line of text is collected from the console via the INLIN standard routine, if Flag C (CTRL-STOP) is returned control transfers to the "STOP" statement handler (63FEH). Otherwise the input string is analyzed and a descriptor created (6638H), control then transfers to the "LET" statement handler for assignment (4892H). It should be noted that the screen is not forced to text mode before the input is collected.

Address... 4B3AH

This is the plain text message "?Redo from start", CR, LF terminated by a zero byte.

5. ROM BASIC INTERPRETER

Address... 4B4DH

This routine is used by the "READ/INPUT" statement handler if it has failed to convert a data item to numeric form. If in "READ" mode (FLGINP is non-zero) a "Syntax error" is generated (404FH). Otherwise the message "?Redo from start" is displayed (6678H) and control returns to the statement handler.

Address... 4B62H

This is the "INPUT#" Statement handler. The buffer number is evaluated and PTRFIL set to direct input from the required I/O buffer (6D55H), control then transfers to the combined "READ/INPUT" statement handler (4B9BH).

Address... 4B6CH

This is the "INPUT" statement handler. If the next program text character is a "#" control transfers to the "INPUT#" statement handler (4B62H). Otherwise the screen is forced to text mode, via the TOTXT standard routine, and any prompt string analyzed (6636H) and displayed (667BH). A question mark is then displayed and a line of text collected from the console via the QINLIN standard routine. If this returns Flag C (CTRL-STOP) control transfers to the "STOP" handler (63FEH). If the first character in BUF is zero (null input) the handler terminates by skipping to the end of the statement (485AH), otherwise control drops into the combined "READ/INPUT" handler.

Address... 4B9FH

This is the "READ" statement handler, a large section is also used by the "INPUT" and "INPUT#" statements so the structure is rather awkward. Each Variable found in the program text is located in turn (5EA4H), for each one the corresponding data item is obtained and assigned to the Variable by the "LET" handler (4893H). When in "READ" mode the data items are taken from the program text using the initial contents of DATPTR (4C40H). When in "INPUT" or "INPUT#" mode the data items are taken from the text buffer BUF.

If the data items are exhausted in "READ" mode an "Out of DATA" error is generated. If they are exhausted in "INPUT" mode two question marks are displayed and another line fetched from the console via the QINLIN standard routine. If they are exhausted in "INPUT#" mode another line of text is copied to BUF from the relevant I/O buffer (6D83H). If the Variable list is exhausted while in "INPUT" mode the message "Extra ignored" is displayed (6678H) and the handler terminates (4AFFH). In "INPUT#" mode no message is displayed while in "READ" mode control terminates by updating DATPTR (63DEH). If a data item cannot be converted to numeric form (3299H) to match a numeric Variable control transfers to the "?Redo from start" routine (4B4DH).

5. ROM BASIC INTERPRETER

Address... 4C2FH

This is the plain text message "?Extra ignored", CR, LF terminated by a zero byte.

Address... 4C40H

This routine is used by the "READ" handler to locate the next "DATA" statement in the program text, the address to start from is supplied in register pair HL. Each program statement is examined until a "DATA" token (84H) is found whereupon the routine terminates (4BD1H). If the end link is reached an "Out of DATA" error is generated. As the search proceeds the line number of each program line is placed in DATLIN for use by the error handler.

Address... 4C5FH

This routine checks that the next character in the program text is the "=" token (EFH) and then drops into the Expression Evaluator. When entered at 4C62H it checks for "(".

Address... 4C64H

This is the Expression Evaluator. On entry register pair HL points to the first character of the expression to be evaluated. On exit register pair HL points to the character following the expression, the result is in DAC and the type code in VALTYP. For a string result the address of the string descriptor is returned at DAC+2. The descriptor itself comprising a single byte for the string length and two bytes for its address, will be in TEMPST or inside a string Variable.

An expression is a list of factors (4DC7H) linked together by operators with differing precedence levels. To process such an expression correctly the Expression Evaluator must be able to temporarily stack an intermediate result, if the next operator has a higher precedence than the current operator, and start afresh on a new calculation. It therefore has two basic operations, STACK and APPLY. For example:

```
3+250\2^2*3^3+1,  
STACK: 3+ (\ follows)  
STACK: 250\ ( follows)  
APPLY: 2^2=4 (* follows)  
STACK: 4* ( follows)  
APPLY: 3^3=27 (+ follows)  
APPLY: 4*27=108 (+ follows)  
APPLY: 250\108=2 (+ follows)  
APPLY: 3+2=5 (+ follows)  
APPLY: 5+1=6 (, follows)
```

Evaluation terminates when the next operator has a precedence

5. ROM BASIC INTERPRETER

equal to or lower than the initial precedence and the stack is empty. The expression delimiter, shown as a comma in the example, is regarded as having a precedence of zero and so will always halt evaluation. Normally the Expression Evaluator starts off with an initial precedence of zero but the entry point at 4C67H may be used to supply an alternative value in register D. This facility is used by the Factor Evaluator to restrict the range of evaluation when applying the monadic negation and "NOT" operators.

Address... 4D22H

This routine is used by the Expression Evaluator to apply an infix math operator (+-*/) to a pair of numeric operands. There are separate routines for the relational operators (4F57H) and the logical operators (4F78H). The first operand, its type code, and the operator token are supplied on the Z80 stack, the second operand and its type code are supplied in DAC and VALTYP. The types of both operands are first compared, if they differ the lowest precision operand is converted to match the higher. The operands are then moved to the positions required by the math routines. For integers the first operand is placed in register pair DE and the second in register pair HL. For single precision the first operand is placed in registers C, B, E, D and the second in DAC. For double precision the first operand is placed in DAC and the second in ARG. The operator token is then used to obtain the required address from the table at 3D51H, 3D5DH or 3D69H, depending upon the operand type, and control transfers to the relevant math routine.

Address... 4DB8H

This routine is used by the Expression Evaluator to divide two integer operands. The first operand is contained in register pair DE and the second in register pair HL, the result is returned in DAC. Both operands are converted to single precision (2FCBH) and control transfers to the single precision division routine (3265H).

Address... 4DC7H

This is the Factor Evaluator. On entry register pair HL points to the character before the factor to be evaluated. On exit register pair HL points to the character following the factor, the result is in DAC and the type code in VALTYP. A factor may be one of the following:

- (1) A numeric or string constant
- (2) A numeric or string Variable
- (3) A function
- (4) A monadic operator (+-NOT)
- (5) A parenthesized expression

The first character is taken from the program text via the

5. ROM BASIC INTERPRETER

CHRGTR standard routine and examined. If it is an end of Statement character a "Missing operand" error is generated (406AH). If it is an ASCII digit it is converted from textual form to one of the standard numeric types in DAC (3299H).

If it is upper case alphabetic (64A8H) it is a Variable and its current value is returned (4E9BH). If it is a numeric token the number is copied from CONLO to DAC (46B8H). If it is one of the FFH prefixed function tokens shown in the table at 39DEH it is decoded to transfer control to the relevant function handler (4ECFH). If it is the monadic "+" operator it is simply skipped over, only the monadic "-" operator (4E8DH) and monadic "NOT" operator (4F63H) require any action.

If it is an opening quote the following explicit string is analyzed and a descriptor created (6636H). If it is an "&" it is a non-decimal numeric constant and it is converted to one of the standard numeric types in DAC (4EB8H). If it is not one of the functions shown below then it must be a parenthesized expression (4E87H), otherwise a "Syntax error" is generated. The following function tokens are tested for directly and control transferred to the address shown:

ERR	4DFDH	ATTR\$	7C43H
ERL	4E0BH	VARPTR ...	4E41H
POINT ..	5803H	USR.....	4FD5H
TIME ...	7900H	INSTR	68EBH
SPRITE .	7A84H	INKEY\$...	7347H
VDP	7B47H	STRING\$..	6829H
BASE ...	7BCBH	INPUT\$...	6C87H
PLAY ...	791BH	CSRLIN ...	790AH
DSKI\$..	7C3EH	FN	5040H

Address... 4DFDH

This routine is used by the Factor Evaluator to apply the "ERR" function. The contents of ERRFLG are placed in DAC as an integer (4FCFH).

Address... 4E0BH

This routine is used by the Factor Evaluator to apply the "ERL" function. The contents of ERRLIN are copied to DAC as a single precision number (3236H).

Address... 4E41H

This routine is used by the Factor Evaluator to apply the "VARPTR" function. If the function token is followed by a "#" the buffer number is evaluated (521BH), the I/O buffer FCB located (6A6DH) and its address placed in DAC as an integer (2F99H). Otherwise the Variable is located (5F5DH) and its address placed in DAC as an integer (2F99H).

5. ROM BASIC INTERPRETER

Address... 4E8DH

This routine is used by the Factor Evaluator to apply the monadic "-" operator. Register D is set to a precedence value of 7DH, the factor evaluated (4C67H) and then negated (2E86H).

Address... 4E9BH

This routine is used by the Factor Evaluator to return the current value of a Variable. The Variable is first located (5EA4H). If it is a string Variable its address is placed in DAC to point to the descriptor. Otherwise the contents of the Variable are copied to DAC (2F08).

Address... 4EA9H

This routine returns the single character pointed to by register pair HL in register A, if it is a lower case alphabetic it converts it to upper case.

Address... 4EB8H

This routine is used by the Factor Evaluator and the numeric input routine (3299H) to convert an ampersand("&") Prefixed number from textual form to an integer in DAC. As each legal character is found the product is multiplied by 2, 8 or 16, depending upon the character which initially followed the ampersand, and the new digit added to it. If the product overflows an "Overflow" error is generated (4067H). The routine terminates when an unacceptable character is found.

Address... 4EFCH

This routine is used by the Factor Evaluator to process the FFH prefixed function tokens. If the token is either "LEFT\$", "RIGHT\$" or "MID\$" the string operand is evaluated (4C62H), the address of its descriptor pushed onto the Z80 stack and the following numeric operand also evaluated (521CH) and stacked. Otherwise the function's parenthesized operand is evaluated (4E87H) and, for "SQR", "RND", "SIN", "LOG", "EXP", "COS", "TAN" or "ATN" only, converted to double precision (303AH). The function token is then used to obtain the required address from the table at 39DEH and control transfers to the function handler.

Address... 4F47H

This routine is used by the numeric input conversion routine (3299H) to test for a "+" or "-" character or token. It returns register D=0 for positive and register D=FFH for negative.

Address... 4F57H

This routine is used by the Expression Evaluator to apply a

5. ROM BASIC INTERPRETER

relational operator (<=> or combinations) to a pair of operands. If the operands are numeric the Expression Evaluator first uses the math operator routine (4D22H) to apply the general relation operation to the operands. If the operands are strings the string comparison routine (65C8H) is used first. When control arrives here the relation result is in register A and the Z80 Flags:

```
Operand 1=Operand 2 ... A=00H, Flag Z,NC
Operand 1<Operand 2 ... A=01H, Flag NZ,NC
Operand 1>Operand 2 ... A=FFH, Flag NZ,C
```

The Expression Evaluator also supplies a bit mask defining the original operators on the Z80 stack. This has a 1 in each position if the associated operation is required: 00000<=>. The mask is applied to the relation result producing zero if none of the conditions is satisfied. This is then placed in DAC as a true (-1) or false (0) integer (2E9AH).

Address... 4F63H

This routine is used by the Factor Evaluator to apply the monadic "NOT" operator. Register D is set to an initial precedence level of 5AH and the expression evaluated (4C67H) and converted to an integer (2F8AH). It is then inverted and restored to DAC.

Address... 4F78H

This routine is used by the Expression Evaluator to apply a logical operator ("OR", "AND", "XOR", "EQV" and "IMP") or the "MOD" and "\" operators to a pair of numeric operands. The first operand, which has already been converted to an integer, is supplied on the Z80 stack and the second is supplied in DAC. The operator token (actually its precedence level) is supplied in register B. After converting the second operand to an integer (2F8AH) the operator is examined. There are separate routines for "MOD" (323AH) and "\" (31E6H) but the logical operators are processed locally using the corresponding Z80 logical instructions on register pairs DE and HL. The result is stored in DAC as an integer (2F99H).

Address... 4FC7H

This routine is used by the Factor Evaluator to apply the "LPOS" function to an operand contained in DAC. The contents of LPTPOS are placed in DAC as an integer (4FCFH).

Address... 4FCCH

This routine is used by the Factor Evaluator to apply the "POS" function to an operand contained in DAC. The contents of TTYPOS are placed in DAC as an integer (2F99).

5. ROM BASIC INTERPRETER

Address... 4FD5H

This routine is used by the Factor Evaluator to apply the "USR" function. The user number is collected directly from the program text, it cannot be an expression, and the associated address taken from USRTAB (4FF4H). The following parenthesized operand is then evaluated (4E87H) and left in DAC as the passed parameter. If it is a string type its storage is freed (67D3H). The current program text position is pushed onto the Z80 stack followed by a return to 3297H, the routine at this address will restore the program text position after the user function has terminated. Control then transfers to the user address with register pair HL pointing to the first byte of DAC and the type code, from VALTYP, in register A. Additionally, for a string parameter, the descriptor address is taken from DAC and placed in register pair DE.

The user routine may modify any register except the Z80 SP and should terminate with a RET instruction, interrupts may be left disabled if necessary as the Runloop will re-enable them. Any numeric parameter to be returned to the Interpreter should be placed in DAC. Strictly speaking this should be the same numeric type as the passed parameter, however if VALTYP is modified the Interpreter will always accept it.

Returning a string type is more difficult. Using the same method as the Factor Evaluator string functions, which involves copying the string to the String Storage Area and pushing a new descriptor onto TEMPST, is complicated and vulnerable to changes in the MSX system. A simpler and more reliable method is to use the passed parameter to create the space for the result. This should not be an explicitly stated string as the program text will have to be modified, instead an implicit parameter should be used. This must be done with care however, it is very easy to gain the impression that the Interpreter has accepted the string when in fact it has not. Take the following example which does nothing but return the passed parameter:

```
10 POKE &H9000,&HC9
20 DEFUSR=&H9000
30 A$=USR(STRING$(12,"!"))
40 PRINT A$
50 B$=STRING$(9,"X")
60 PRINT A$
```

At first it seems that the passed string has been correctly assigned to A\$. When line 60 is reached however it becomes apparent that A\$ has been corrupted by the subsequent assignment of a string to B\$. What has happened is that the temporary storage allocated to the passed parameter was reclaimed from the String Storage Area before control transferred to the user routine. This region was then used to store the string belonging to B\$ thus modifying A\$.

5. ROM BASIC INTERPRETER

This situation can be avoided by assigning the parameter to a Variable beforehand and then passing the Variable, for example:

```
10 A$=STRING$(12,"!")
20 A$=USR(A$)
```

Line 10 results in twelve bytes of the String Storage Area being permanently allocated to A\$. When the user function is entered the descriptor, which is pointed to by register pair DE, will contain the starting address of the twelve byte region where the result should be placed. If the returned string is shorter than the passed one the length byte of the descriptor may be changed without any side effects. For further details on string storage see the garbage collector (66B6H).

A point worth noting is that a "CLEAR" operation is not strictly necessary before a machine language program is loaded. The region between the top of the Array Storage Area and the base of the Z80 stack is never used by the Interpreter. A program can exist in this region provided that the two enclosing areas do not overlap it.

Address... 500EH

This is the "DEFUSR" statement handler. The user number is collected directly from the program text, it cannot be an expression, and the associated entry in USRTAB located (4FF4H). The address operand is then evaluated (542FH) and placed in USRTAB.

Address... 501DH

This is the "DEF FN" and "DEFUSR" statement handler. If the following character is a "USR" token (DDH) control transfers to the "DEFUSR" statement handler (500EH), otherwise the program text is checked for a trailing "FN" token (DEH). The function name Variable is located (51A1H) and, after checking that the Interpreter is in program mode (5193H), the current program text position is placed there. Each of the Variables in the formal parameter list is then located in succession (5EA4H), this is simply to ensure that they are created. The routine terminates by skipping over the remainder of the statement (485BH) as the function body is not required at this time.

Address... 5040H

This routine is used by the Factor Evaluator to apply the "FN" function. The function name Variable is first located (51A1H) to obtain the address of the function definition in the program text. Each formal Variable from the function definition is located in turn (5EA4H) and its address pushed onto the Z80 stack. As each one is found the corresponding actual parameter is evaluated (4C64H) and pushed onto the stack with it. If

5. ROM BASIC INTERPRETER

necessary the type of the actual parameter is converted to match that of the formal parameter (517AH)'

When both lists are exhausted each formal Variable address and actual parameter are popped from the stack in turn. Each Variable is then copied from the Variable Storage Area to PARM2 with its value replaced by the actual parameter. It should be noted that, because PARM2 is only a hundred bytes long, a maximum of nine double precision parameters is allowed. When all the actual parameters have been copied to PRM2 the entire contents of PARM1 (the current parameter area) are pushed onto the Z80 stack and PARM2 is copied to PARM1 (518EH). Register pair HL is then set to the start of the function body in the program text and the expression is evaluated (4C5FH). The old contents of PARM1 are popped from the stack and restored. Finally the result of the evaluation is type converted if necessary to match the function name type (517AH).

A user defined function differs from a normal expression in only one respect, it has its own set of local Variables. These Variables are created in PARM1 when the function is invoked and disappear when it terminates. When a normal Variable search is initiated by the Expression Evaluator the region examined is the Variable Storage Area. However, if NOFUNS is non-zero, indicating at least one active user function, PARM1 will be searched instead, only if this fails will the search move on to the global Variables in the Variable Storage Area. Using a local Variable area specific to each invocation of a function means that the same Variable names can be used throughout without the Variables overwriting each other or the global Variables.

It is worth noting that a user defined function is slower than an inline expression or even a subroutine. The search carried out to find the function name Variable, plus the large amount of stacking and destacking, are significant overheads.

Address... 5189H

This routine moves a block of memory from the address pointed to by register pair DE to that pointed to by register pair HL, register pair BC defines the length.

Address... 5193H

This routine generate an "Illegal direct" error if CURLIN shows the Interpreter to be in direct mode.

Address... 51A1H

This routine checks the program text for an "FN" token (DEH) and then creates the function name Variable (5EA9H). These are distinguished from ordinary Variables by having bit 7 set in the first character of the Variable's name.

5. ROM BASIC INTERPRETER

Address... 51ADH

Control transfers to this routine from the Runloop execution point (4640H) if a token greater than D8H is found at the start of a statement. If the token is not an FFH prefixed function token a "Syntax error" is generated (4055H). If the function token is one of those which double as statements control transfers to the relevant handler, otherwise a "Syntax error" is generated. The statements in question are "MID\$" (696EH), "STRIG" (77BFH) and "INTERVAL" (77B1H). There is actually no separate token for "INTERVAL", the "INT" token (85H) suffices with the remaining characters being checked by the statement handler.

Address... 51C9H

This is the "WIDTH" statement handler. The operand is evaluated (521CH) and its magnitude checked. If it is zero or greater than thirty-two or forty, depending upon the screen mode held in OLDSCR an "Illegal function call" error is generated (475AH). If it is the same as the current contents of LINLEN the routine terminates with no further action. Otherwise the current screen is cleared with a FORMFEED control code (0CH) via the OUTDO standard routine in case the screen is to be made smaller. The operand is then placed in LINLEN and either LINL32 or LINL40, depending upon the screen mode held in OLDSCR, and the screen cleared again in case it has been made larger. Because the line length variable to be changed is selected by OLDSCR, rather than SCRMOD, the width can still be changed even if the screen is currently in Graphics Mode or Multicolour Mode. In this case the change is effective when a return is made to the Interpreter Mainloop or an "INPUT" statement is executed.

Address... 520EH

This routine evaluates the next expression in the program text (4C64H), converts it to an integer (2F8AH) and places the result in register pair DE. The magnitude and sign of the MSB are then tested and the routine terminates.

Address... 521BH

This routine evaluates the next operand in the program text (4C64H) and converts it to an integer (5212H). If the operand is greater than 255 an "Illegal function call" error is generated (475AH).

Address... 5229H

This is the "LLIST" statement handler. PRTFLG is set to 01H, to direct output to the printer, and control drops into the "LIST" statement handler.

5. ROM BASIC INTERPRETER

Address... 522EH

This is the "LIST" statement handler. The optional start and termination line number operands are collected and the starting position found in the program text (4279H). Successive program lines are listed until the end link is found, the CTRL-STOP key is pressed or the termination line number is reached, control then transfers directly to the Mainloop "OK" point (411FH). Each program line is listed by displaying its line number (3412H), detokenizing (5284H) and displaying (527BH) the line itself and then issuing a CR,LF (7328H).

Address... 5284H

This routine is used by the "LIST" statement handler to convert a tokenized program line to textual form. On entry register pair HL points to the first character of the tokenized line. On exit the line of text is in BUF and is terminated by a zero byte.

Any normal or FFH prefixed token is converted to the corresponding keyword by a simple linear search of the tokens in the table at 3A72H. Exceptions are made if either an opening quote character, a "REM" token, or a "DATA" token has previously been found. Normally these tokens will be followed by plain text anyway, the check is made to stop graphics characters being interpreted as tokens. The three byte sequence ":" (3AH), "REM" token (8FH), " " token (E6H) is converted to the single " " character (27H) and the statement separator (3AH) preceding an "ELSE" token (A1H) is scrubbed out.

If one of the numeric tokens is found its value and type are first copied from CONLO and CONTYP to DAC and VALTYP (46E8H). It is then converted to textual form in FBUFR by the decimal (3425H), octal (371EH) or hex (3722H) conversion routines. For octal and hex types the number is prefixed by an ampersand and an "O" or "H" letter. A type suffix, "." or "#", is added to single precision or double precision numbers only if there is no decimal part and no exponent part ("E" or "D").

Address... 53E2H

This is the "DELETE" statement handler. The optional start and termination line number operands are collected and the starting position found in the program text (4279H). If any pointers exist in the program text they are converted back to line numbers (54EAH). The terminating program line is found by a search of the program text (4295H), if this address is smaller than that of the starting program line an "Illegal function call" error is generated (475AH), otherwise the message "OK" is displayed (6678H). The block of memory from the end of the terminating line to the start of the Variable Storage Area is copied down to the beginning of the starting line and VARTAB, ARYTAB and STREND are reset to the new (lower)

5. ROM BASIC INTERPRETER

end of the program text. Control then transfers directly to the end of the Mainloop (4237H) to reset the remaining pointers and to relink the Program Text Area. Note that, because control does not return to the normal "OK" point, the screen will not be returned to text mode. If the screen is in Graphics Mode or Multicolour mode when a "DELETE" is executed, which is admittedly rather unlikely, the system will crash.

Address... 541CH

This routine is used by the Factor Evaluator to apply the "PEEK" function to an operand contained in DAC. The address operand is checked (5439H) then the byte read from memory and placed in DAC as an integer (4FCFH).

Address... 5423H

This is the "POKE" statement handler. The address operand is evaluated (542FH) then the data operand evaluated (521CH) and written to memory.

Address... 542FH

This routine evaluates the next operand in the program text (4C64H) and places it in register pair DE as an integer (5439H).

Address... 5439H

This routine converts the numeric operand contained in DAC into an integer in register pair HL. The operand must be in the range -32768 to +65535 and is normally an address as required by "POKE", "PEEK", "BLOAD", etc. The operand's type is first checked via the GETYPR standard routine, if it is already an integer it is simply placed in register pair HL (2F8AH). Assuming the operand is single precision or double precision its sign is checked, if it is negative it is converted to integer (2F8AH). Otherwise it is converted to single precision (2FB2H) and its magnitude checked (2F21H). If it is greater than 32767 and smaller than 65536 then -65536 is added (324EH) before it is converted to integer (2F8AH).

Address... 5468H

This is the "RENUM" statement handler. If a new initial line number operand exists it is collected (475FH), otherwise a default value of ten is taken. If an old initial line number operand exists it is collected (475FH), otherwise a default value of zero is taken. If an increment line number operand exists it is collected (4769H), otherwise a default value of ten is taken.

The program text is then searched for existing line numbers equal to or greater than the new initial line number (4295H)

5. ROM BASIC INTERPRETER

and the old initial line number (4295H), an "Illegal function call" error is generated (475AH) if the new address is smaller than the old address. This is to catch any attempt to renumber high program lines down to existing low ones.

A dummy renumbering run of the program text is first carried out to check that no new line number will be generated with a value greater than 65529. This must be done as an error midway through the conversion would leave the program text in a confused state. Assuming all is well any line number operands in the program text are converted to pointers (54F6H). This neatly solves the problem of line number references, GOTO 50 for example, as the program text is not moved during renumbering. Starting at the old initial program text position each existing program line number is replaced with its new value. When the end link is reached any program text pointers are converted back to line number operands (54F1H) and control transfers directly to the Mainloop "OK" point (411EH).

Address... 54F6H

When entered at 54F6H this routine converts every line number operand in the program text to a pointer. When entered at 54F7H it performs the reverse operation and converts every pointer in the program text back to a line number operand. Starting at the beginning of the Program Text Area each line is examined for a pointer token (0DH) or a line number operand token (0EH) depending upon the mode. In pointer to line number operand mode the pointer is replaced by the line number from the referenced program line and the token changed to 0EH. In line number operand to pointer mode the program text is searched (4295H) to find the relevant line, its address replaces the line number operand and the token is changed to 0DH. If the search is unsuccessful a message of the form "Undefined line NNNN in NNNN" is displayed (6678H) and the conversion process continues. A special check is made for the "ON ERROR GOTO 0" statement, to prevent the generation of a spurious error message, but no check is made for the similar "RESUME 0" statement. In this case an error message will be displayed, this should be ignored.

Address... 555AH

This is the plain text message "Undefined line " terminated by a zero byte.

Address... 558CH
Name..... SYNCHR
Entry..... HL points to character to check
Exit..... A=Next program character
Modifies.. AF, HL

Standard routine to check the current program text character, whose address is supplied in register pair HL,

5. ROM BASIC INTERPRETER

against a reference character. The reference character is supplied as a single byte immediately following the CALL or RST instruction, for example:

```
RST 08H
DEFB ", "
```

If the characters do not match a "Syntax error" is generated (4055H), otherwise control transfers to the CHRGT standard routine to fetch the next program character (4666H).

```
Address... 5597H
Name..... GETYPR
Entry..... None
Exit..... AF=Type
Modifies.. AF
```

Standard routine to return the type of the current operand, determined by VALTYP, as follows:

```
Integer.....A=FFH, Flag M,NZ,C
String.....A=00H, Flag P,Z,C
Single Precision ... A=01H, Flag P,NZ,C
Double Precision ... A=05H, Flag P,NZ,NC
```

```
Address... 55A8H
```

This is the "CALL" statement handler. The extended statement name, which is an unquoted string up to fifteen characters long terminated by a "(", ":", or end of line character (00H), is first copied from the program text to PROCNM, any unused bytes are zero filled. Bit 5 of each entry in SLTATR is then examined for an extension ROM with a statement handler. If a suitable ROM is found its position in SLTATR is converted to a Slot ID in register A and a ROM base address in register H (7E2AH). The statement handler address is read from ROM locations four and five (7E1AH) and placed in register pair IX. The Slot ID is placed in the high byte of register pair IY and the ROM statement handler called via the CALSLT standard routine.

The ROM will examine the statement name and return Flag C if it does not recognize it, otherwise it performs the required operation. If the ROM call fails the search of SLTATR continues until the table is exhausted whereupon a "Syntax error" is generated (4055H). If the ROM call is successful the handler terminates.

```
Address... 55F8H
```

This routine is used by the device name parser (6F15H) when it cannot recognize a device name found in the program text. Upon entry register pair HL points to the first character of the name and register B holds its length. The name is first copied to PROCNM and terminated by a zero byte. Bit 6 of each

5. ROM BASIC INTERPRETER

entry in SLTATR is then examined for an extension ROM with a device handler. If a suitable ROM is found its position in SLTATR is converted to a Slot ID in register A and a ROM base address in register H (7E2AH). The device handler address is read from ROM locations six and seven (7E1AH) and placed in register pair IX. The Slot ID is placed in the high byte of register pair IY, the unknown device code (FFH) in register A and the ROM device handler called via the CALSLT standard routine.

The ROM will examine the device name and return Flag C if it does not recognize it, otherwise it returns its own internal code from zero to three. If the ROM call fails the search of SLTATR continues until the table is exhausted whereupon a "Bad file name" error is generated (6E6BH). If the ROM call is successful the ROM's internal code is added to its SLTATR position, multiplied by a factor of four, to produce a global device code. The base code for each entry in SLTATR is shown below in hexadecimal. The "SS" and "PS" markers show the corresponding Secondary and Primary Slot numbers, each slot is composed of four pages:

SS0	SS1	SS2	SS3	
UAA;				
3 00 04 08 0C	3 10 14 18 1C	3 20 24 28 2C	3 30 34 38 3C	3 PS0
AAA'				
3 40 44 48 4C	3 50 54 58 5C	3 60 64 68 6C	3 70 74 78 7C	3 PS1
AAA'				
3 80 84 88 8C	3 90 94 98 9C	3 A0 A4 A8 AC	3 B0 B4 B8 BC	3 PS2
AAA'				
3 C0 C4 C8 CC	3 D0 D4 D8 DC	3 E0 E4 E8 EC	3 F0 F4 F8 FC	3 PS3
AAU				

Figure 44: Device Codes

The global device code is used by the Interpreter until the time comes for the ROM to perform an actual device operation. It is then converted back into the ROM's Slot ID, base address and internal device code to perform the ROM access. Note that the codes from 0 to 8 are reserved for disk drive identifiers and those from FCH to FFH for the standard devices GRP, CRT, LPT and CAS. With the current MSX hardware structure these codes correspond to physically improbable ROM configurations and are therefore safe to be used for specific purposes by the Interpreter.

Address... 564AH

This routine is used by the function dispatcher (6F8FH) when it encounters a device code not belonging to one of the standard devices. The device code is first converted to a SLTATR position and then to a Slot ID in register A and ROM base address in register H (7E2DH). The ROM device handler

5. ROM BASIC INTERPRETER

address is read from ROM locations six and seven (7E1AH) and placed in register pair IX. The Slot ID is placed in the high byte of register pair IY, the ROM's internal device code in DEVICE and the ROM device handler called via the CALSLT standard routine.

Address... 566CH

This entry point to the macro language parser is used by the "DRAW" statement handler, a later entry point (56A2H) is used by the "PLAY" statement handler. The command string is evaluated (4C64H) and its storage freed (67D0H). After pushing a zero termination block onto the Z80 stack the length and address of the string body are placed in MCLLEN and MCLPTR and control drops into the parser mainloop.

Address... 56A2H

This is the macro language parser mainloop, it is used to process the command string associated with a "DRAW" or "PLAY" statement. On entry the string length is in MCLLEN, the string address is in MCLPTR and the address of the relevant command table is in MCLTAB. The command tables contain the legal command letters, together with the associated command handler addresses, for each statement. The "DRAW" table is at 5D83H and the "PLAY" table at 752EH.

The parser mainloop first fetches the next character from the command string (56EEH). If there are no more characters left the next string descriptor is popped from the stack (568CH). If this is zero the parser terminates (5709H) if MCLFLG shows a "DRAW" statement to be active, otherwise control transfers back to the "PLAY" statement handler (7494H).

Assuming a command character exists the current command table is searched to check its legality, if no match is found an "Illegal function call" error is generated (475AH). The command table entry is then examined, if bit 7 is set the command takes an optional numeric parameter. If this is present it is collected and placed in register pair DE (571CH), otherwise a default value of one is taken. After pushing a return to the start of the parser mainloop onto the Z80 stack control transfers to the command handler at the address taken from the command table.

Address... 56EEH

This routine is used by the macro language parser to fetch the next character from the command string. If MCLLEN is zero the routine terminates with Flag Z, there are no characters left. Otherwise the next character is taken from the address contained in MCLPTR and returned in register A, if the character is lower case it is converted to upper case. MCLPTR is then incremented and MCLLEN decremented Ed.

5. ROM BASIC INTERPRETER

Address... 570BH

This routine is used by the macro language parser to return an unwanted character to the command string. MCLLEN is incremented and MCLPTR decremented.

Address... 5719H

This routine is used by the macro language parser to collect a numeric parameter from the command string. The result is a signed integer and is returned in register pair DE, it cannot be an expression. The first character is taken and examined, if it is a "+" it is ignored and the next character taken (5719H). If it is a "-" a return is set up to the negation routine (5795H) and the next character taken (5719H). If it is an "=" the value of the following Variable is returned (577AH). Otherwise successive characters are taken and a binary product accumulated until a non-numeric character is found.

Address... 575AH

This routine is used by the macro language parser "=" and "X" handlers. The Variable name is copied to BUF until the ";" delimiter is found, if this takes more than thirty-nine characters to find an "Illegal function call" error is generated (475AH). Otherwise control transfers to the Factor Evaluator Variable handler (4E9BH) and the Variable contents are returned in DAC.

Address... 577AH

This routine is used by the macro language parser to process the "=" character in a command parameter. The Variable's value is obtained (575AH), converted to an integer (2F8AH) and placed in register pair DE.

Address... 5782H

This routine is used by the macro language parser to process the "X" command. The Variable is processed (575AH) and, after checking that stack space is available (625EH), the current contents of MCLLEN and MCLPTR are stacked. Control then transfers to the parser entry point (5679H) to obtain the Variable's descriptor and process the new command string.

Address... 579CH

This routine is used by various graphics statements to evaluate a coordinate pair in the program text. The coordinates must be parenthesized with a comma separating the component operands. If the coordinate pair is preceded by a "STEP" token (DCH) each component value is added to the corresponding component of the current graphics coordinates in GRPACX and GRPACY, otherwise the absolute values are returned. The X

5. ROM BASIC INTERPRETER

coordinate is returned in GRPACX, GXPOS and register pair BC. The Y coordinate is returned in GRPACY, GYPOS and register pair DE.

There are two entry points to the routine, the one which is used depends on whether the caller is expecting more than one coordinate pair. The "LINE" statement, for example, expects two coordinate pairs the first of which is the more flexible. The entry point at 579CH is used to collect the first coordinate pair and will accept the characters "-" or "@-" as representing the current graphics coordinates. The entry point at 57ABH is used for the second coordinate pair and requires an explicit operand.

Address... 57E5H

This is the "PRESET" statement handler. The current background colour is taken from BAKCLR and control drops into the "PSET" handler.

Address... 57EAH

This is the "PSET" statement handler. After the coordinate pair has been evaluated (57ABH) the current foreground colour is taken from FORCLR and used as the default when setting the ink colour (5850H). The current graphics coordinates are converted to a physical address, via the SCALXY and MAPXYC standard routines, and the colour of the current pixel set via the SETC standard routine.

Address... 5803H

This routine is used by the Factor Evaluator to apply the "POINT" function. The current contents of CLOC, CMASK, GYPOS, GXPOS, GRPACY and GRPACX are stacked and the coordinate pair operand evaluated (57ABH). The colour of the new pixel is read via the SCALXY, MAPXYC and READC standard routines and placed in DAC as an integer (2F99H), the old coordinate values are then popped and restored. Note that a value of -1 is returned if the point coordinates are outside the screen.

Address... 5850H

This graphics routine is used to evaluate an optional colour operand in the program text and to make it the current ink colour. After checking the screen mode (59BCH) the colour operand is evaluated (521CH) and placed in ATRBYT. If no operand exists the colour code supplied in register A is placed in ATRBYT instead.

Address... 5871H

This graphics routine returns the difference between the contents of GXPOS and register pair BC in register pair HL. If

5. ROM BASIC INTERPRETER

the result is negative (GXPOS<BC) it is negated to produce the absolute magnitude and Flag C is returned.

Address... 5883H

This graphics routine returns the difference between the contents of GYPOS and register pair DE in register pair HL. If the result is negative (GYPOS<DE) it is negated to produce the absolute magnitude and Flag C is returned.

Address... 588EH

This graphics routine swaps the contents of GYPOS and register pair DE.

Address... 5898H

This graphics routine first swaps the contents of GYPOS and register pair DE (588EH) then swaps the contents of GXPOS and register pair BC. When entered at 589BH only the second operation is performed.

Address... 58A7H

This is the "LINE" statement handler. The first coordinate pair (X1,Y1) is evaluated (579CH) and placed in register pairs BC,DE. After checking for the "-" token (F2H) the second coordinate pair (X2,Y2) is evaluated (57ABH) and left in GRPACX, GRPACY and GXPOS, GYPOS. After setting the ink colour (584DH) the program text is checked for a following "B" or "BF" option and either the box (5912H), boxfill (58BFH) or linedraw (58FCH) operation performed. None of these operations affects the current graphics coordinates in GRPACX and GRPACY, these are left at X2,Y2.

Address... 58BFH

This routine performs the boxfill operation. Given that the supplied coordinate pairs define diagonally opposed points of the box two quantities must be derived from them. The horizontal size of the box is obtained from the difference between X1 and X2, this gives the number of pixels to set per row. The vertical size is obtained from the difference between Y1 and Y2 giving the number of rows required. Starting at the physical address of X1,Y1, and moving successively lower via the DOWNC standard routine, the required number of pixel rows are filled in by repeated use of the NSETCX standard routine.

Address... 58FCH

This routine performs the linedraw operation. After drawing the line (593CH) GXPOS and GYPOS are reset to X2,Y2 from GRPACX and GRPACY.

5. ROM BASIC INTERPRETER

Address... 5912H

This routine performs the box operation. The box is produced by drawing a line (58FCH) between each of the four corner points. The coordinates of each corner are derived from the initial operands by interchanging the relevant component of the pair. The drawing sequence is:

- (1) X1,Y2 to X2,Y2
- (2) X1,Y1 to X2,Y1
- (3) X2,Y1 to X2,Y2
- (4) X1,Y1 to X1,Y2

Address... 593CH

This routine draws a line between the points X1,Y1, supplied in register pairs BC and DE and X2,Y2, supplied in GXPOS and GYPOS. The operation of the drawing mainloop (5993H) is best illustrated by an example, say LINE(0,0)-(10,4). To reach the end point of the line from its start ten horizontal steps (X2-X1) and four downward steps (Y2-Y1) must be taken altogether. The best approximation to a straight line therefore requires two and a half horizontal steps for every downward step (X2-X1/Y2-Y1). While this is impossible in practice, as only integral steps can be taken, the correct ratio can be achieved on average.

The method employed is to add the Y difference to a counter each time a rightward step is taken. When the counter exceeds the value of the X difference it is reset and one downward step is taken, this is in effect an integer division of the two difference values. Sometimes downward steps will be produced every two rightward steps and sometimes every three rightward steps. The average, however, will be one downward step every two and a half rightward steps. An equivalent BASIC program is shown below with a slightly offset BASIC line for comparison:

```
10 SCREEN 0
20 INPUT"START X,Y";X1,Y1
30 INPUT"END X,Y",X2,Y2
40 SCREEN 2
50 X=X1:Y=Y1:L=X2-X1:S=Y2-Y1:CTR=L/2
60 PSET(X,Y)
70 CTR=CTR+S:IF CTR<L THEN 90
80 CTR=CTR-L:Y=Y+1
90 X=X+1:IF X<=X2 THEN 60
100 LINE(X1,Y1+5)-(X2,Y2+5)
110 GOTO 110
```

The above example suffers from three limitations. The line must slope downwards, it must slope to the right and the slope cannot exceed forty-five degrees from the horizontal (one downward step for one rightward step).

5. ROM BASIC INTERPRETER

The routine overcomes the first limitation by examining the Y1 and Y2 coordinates before drawing commences. If Y2 is greater than or equal to Y1, showing the line to slope upwards or to be horizontal, both coordinate pairs are exchanged. The line is now sloping downwards and will be drawn from the end point to the start.

The second limitation is overcome by examining X1 and X2 beforehand to determine which way the line is sloping. If X2 is greater than or equal to X1 the line slopes to the right and a Z80 JP to the RIGHTC standard routine is placed in MINUPD/MAXUPD (see below) for use by the drawing mainloop, otherwise a JP to the LEFTC standard routine is placed there.

The third limitation is overcome by comparing the X coordinate difference to the Y coordinate difference before drawing to determine the slope steepness. If X2-X1 is smaller than Y2-Y1 the slope of the line is less than forty-five degrees from the horizontal. The simple method shown above for LINE(0,0)-(10,4) will not work for slopes greater than forty-five degrees as the maximum rate of descent is achieved when one downward step is taken for every horizontal step. It will work however if the step directions are exchanged. Thus LINE(0,0)-(4,10) requires one rightward step for every two and a half downward steps. MINUPD holds a Z80 JP to the "normal" step direction standard routine for the drawing mainloop and MAXUPD holds a JP to the "slope" step direction standard routine. For shallow angles MINUPD will vector to DOWNC and MAXUPD to LEFTC or RIGHTC. For steep angles MINUPD will vector to LEFTC or RIGHTC and MAXUPD to DOWNC. For steep angles the counter values must also be exchanged, the X difference must now be added to the counter and the Y difference used as the counter limit. The variables MINDEL and MAXDEL are used by the drawing mainloop to hold these counter values, MINDEL holds the smaller end point difference and MAXDEL the larger.

An interesting point is that the reference counter, held in CTR in the above program and in register pair DE in the ROM, is preloaded with half the largest end point difference rather than being set to zero. This has the effect of splitting the first "stair" in the line into two sections, one at the start of the line and one at its end, and improving the line's appearance.

Address... 59B4H

This graphics routine shifts the contents of register pair DE one bit to the right.

Address... 59BCH

This routine generates an "Illegal function call" error (475AH) if the screen is not in Graphics Mode or Multicolour Mode.

5. ROM BASIC INTERPRETER

Address... 59C5H

This is the "PAINT" statement handler. The starting coordinate pair is evaluated (579CH), the ink colour set (584DH) and the optional boundary colour operand evaluated (521CH) and placed in BDRATR. The starting coordinate pair is checked to ensure that it is within the screen (5E91H) and is made the current pixel physical address by the MAPXYC standard routine. The distance to the right hand boundary is then measured (5ADCH) and, if it is zero, the handler terminates. Otherwise the distance to the left hand boundary is measured (5AEDH) and the sum of the two placed in register pair DE as the zone width. The current position is then stacked twice (5ACEH), first with a termination flag (00H) and then with a down direction flag (40H). Control then transfers to the paint mainloop (5A26H) with an up direction flag (C0H) in register B.

Address... 5A26H

This is the paint mainloop. The zone width is held in register pair DE, the paint direction, up or down, in register B and the current pixel physical address is that of the pixel adjacent to the left hand boundary. A vertical step is taken to the next line, via the TUPC or TDOWNC standard routines, and the distance to the right hand boundary measured (5ADCH). The distance to the left hand boundary is then measured and the line between the boundaries filled in (5AEDH). If no change is found in the position of either boundary control transfers to the start of the mainloop to continue painting in the same direction. If a change is found an inflection has occurred and the appropriate action must be taken.

There are four types of inflection, LH or RH incursive, where the relevant boundary moves inward, and LH or RH excursive, where it moves outward. An example of each type is shown below with numbered zones indicating the order of painting during upward movement. A secondary zone is shown within each inflective region for completeness:

Figure 45: Boundary Inflections

A LH excursion has occurred when the distance to the left hand boundary is non-zero, a RH excursion has occurred when the

5. ROM BASIC INTERPRETER

current zone width is greater than that of the previous line. Unless the excursion is less than two pixels, in which case it will be ignored, the current position (the bottom left of zone 3 in figure 45) is stacked (5AC2H), the paint direction reversed and painting restarts at the top left of the excursive region .

A RH incursion has occurred when the current zone width is smaller than that of the previous line. If the incursion is total, that is the current zone width is zero, a dead end has been reached and the last position and direction are popped (5AIFH) and painting restarts at that point. Otherwise the current position and direction are stacked (5AC2H) and painting restarts at the bottom left of the incursive region.

A LH incursion is dealt with automatically during the search for the right hand boundary and requires no explicit action by the paint mainloop.

Address... 5AC2H

This routine is used by the "PAINT" statement handler to save the current paint position and direction on the Z80 stack. The six byte parameter block is made up of the following:

- 2 bytes ... Current contents of CLOC
- 1 byte ... Current direction
- 1 byte ... Current contents of CMASK
- 2 bytes ... Current zone width

After the parameters have been stacked a check is made that sufficient stack space still exists (625EH).

Address... 5ADCH

This routine is used by the "PAINT" statement handler to locate the right hand boundary. The zone width of the previous line is passed to the SCANR standard routine in register pair DE, this determines the maximum number of boundary colour pixels that may initially be skipped over. The returned skip count remainder is placed in SKPCNT and the number of non-boundary colour pixels traversed in MOVCNT.

Address... 5AEDH

This routine is used by the "PAINT" statement handler to locate the left hand boundary. The end point of the right hand boundary search is temporarily saved and the starting point taken from CSAVEA and CSAVEM and made the current pixel physical address. The left hand boundary is then located via the SCANL standard routine, which also fills in the entire zone, and the right hand end point recovered and placed in CSAVEA and CSAVEM.

5. ROM BASIC INTERPRETER

Address... 5B0BH

This routine is used by the "CIRCLE" statement handler to negate the contents of register pair DE.

Address... 5B11H

This is the "CIRCLE" statement handler. After evaluating the centre coordinate pair (579CH) the radius is evaluated (520FH), multiplied (325CH) by SIN(PI/4) and placed in CNPNTS. The ink colour is set (584DH), the start angle evaluated (5D17H) and placed in CSTCNT and the end angle evaluated (5D17H) and placed in CENCNT. If the end angle is smaller than the start angle the two values are swapped and CPLOTF is made non-zero. The aspect ratio is evaluated (4C64H) and, if it is greater than one, its reciprocal is taken (3267H) and CSCLXY is made non-zero to indicate an X axis squash. The aspect ratio is multiplied (325CH) by 256, converted to an integer (2F8AH) and placed in ASPECT as a single byte binary fraction. Register pairs HL and DE are set to the starting position on the circle perimeter (X=RADIUS,Y=0) and control drops into the circle mainloop.

Address... 5BBDH

This is the circle mainloop. Because of the high degree of symmetry in a circle it is only necessary to compute the coordinates of the arc from zero to forty-five degrees. The other seven segments are produced by rotation and reflection of these points. The parametric equation for a unit circle, with T the angle from zero to PI/4, is:

$$\begin{aligned} X &= \text{COS}(T) \\ Y &= \text{SIN}(T) \end{aligned}$$

Direct computation using this equation, or the corresponding functional form $X = \text{SQR}(1 - Y^2)$, is too slow, instead the first derivative is used:

$$\frac{dx}{dy} = -Y/X$$

Given that the starting position is known (X=RADIUS,Y=0), the X coordinate change for each unit Y coordinate change may be computed using the derivative. Furthermore, because graphics resolution is limited to one pixel, it is only necessary to know when the sum of the X coordinate changes reaches unity and then to decrement the X coordinate. Therefore:

$$\begin{aligned} \text{Decrement X when } (Y1/X) + (Y2/X) + (Y3/X) + \dots &=> 1 \\ \text{Therefore decrement when } (Y1+Y2+Y3+\dots)/X &=> 1 \\ \text{Therefore decrement when } Y1+Y2+Y3+\dots &=> X \end{aligned}$$

All that is required to identify an X coordinate change is to totalize the Y coordinate values from each step until the X

5. ROM BASIC INTERPRETER

coordinate value is exceeded. The circle mainloop holds the X coordinate in register pair HL, the Y coordinate in register pair DE and the running total in CRCSUM. An equivalent BASIC program for a circle of arbitrary radius 160 pixels is:

```
10 SCREEN 2
20 X=160:Y=0:CRCSUM=0
30 PSET(X,191-Y)
40 CRCSUM=CRCSUM+Y :Y=Y+1
50 IF CRCSUM<X THEN 30
60 CRCSUM=CRCSUM-X:X=X-1
70 IF X>Y THEN 30
80 CIRCLE(0,191),155
90 GOTO 90
```

The coordinate pairs generated by the mainloop are those of a "virtual" circle, such tasks as axial reflection, elliptic squash and centre translation are handled at a lower level (5C06H).

Address... 5C06H

This routine is used to by the circle mainloop to convert a coordinate pair, in register pairs HL and DE, into eight symmetric points on the screen. The Y coordinate is initially negated (5B0BH), reflecting it about the X axis, and the first four points produced by successive clockwise rotations through ninety degrees (5C48H). The Y coordinate is then negated again (5B0BH) and a further four points produced (5C48H).

Clockwise rotation is performed by exchanging the X and Y coordinates and negating the new Y coordinate, thus a point (40,10) would become (10,-40). Assuming an aspect ratio of 0.5, for example, the complete sequence of eight points would therefore be:

```
(1) X,-Y*0.5
(2) -Y,-X*0.5
(3) -X, Y*0.5
(4) Y, X*0.5
(5) Y,-X*0.5
(6) -X,-Y*0.5
(7) -Y, X*0.5
(8) X, Y*0.5
```

It can be seen from the above that, ignoring the sign of the coordinates for the moment, there are only four terms involved. Therefore, rather than performing the relatively slow aspect ratio multiplication (5CEBH) for each point, the terms $X*0.5$ and $Y*0.5$ can be prepared in advance and the complete sequence generated by interchanging and negating the four terms. With the aspect ratio shown above the initial conditions are set up so that register pair HL=X, register pair DE= $-Y*0.5$, CXOFF=Y and CYOFF= $X*0.5$ and successive points are produced by the

5. ROM BASIC INTERPRETER

operations:

- (1) Exchange HL and CXOFF, negate HL.
- (2) Exchange DE and CYOFF, negate DE.

In parallel with the computation of each circle coordinate the number of points required to reach the start of the segment containing the point is kept in CPCNT8. This will initially be zero and will increase by $2 * \text{RADIUS} * \text{SIN}(\text{PI}/4)$ as each ninety degree rotation is made. As each of the eight points is produced its Y coordinate value is added to the contents of CPCNT8 and compared to the start and end angles to determine the appropriate course of action. If the point is between the two angles and CPLOTf is zero, or if it is outside the angles and CPLOTf is non-zero, the coordinates are added to the circle centre coordinates (5CDCH) and the point set via the SCALXY, MAPXYC and SETC standard routines. If the point is equal to either of the two angles, and the associated bit is set in CLINEF, the coordinates are added to the circle centre coordinates (5CDCH) and a line drawn to the centre (593CH). If none of these conditions is applicable no action is taken other than to proceed to the next point.

Address... 5CEBH

This routine multiplies the coordinate value supplied in register pair DE by the aspect ratio contained in ASPECT, the result is returned in register pair DE. The standard binary shift and add method is used but the operation is performed as two single byte multiplications to avoid overflow problems.

Address... 5D17H

This routine is used by the "CIRCLE" statement handler to convert an angle operand to the form required by the circle mainloop, the result is returned in register pair DE. While the method used is basically sound, and eliminates one trigonometric computation per angle, the results produced are inaccurate. This is demonstrated by the following example which draws a line to the true thirty degree point on a circle's perimeter:

```
10 SCREEN 2
20 PI = 4 * ATN(1)
30 CIRCLE(100,100),80,,PI/6
40 LINE(100,100)-(100+80*COS(PI/6),100-80*SIN(PI/6))
50 GOTO 50
```

The result that the routine should produce is the number of points that must be produced by the circle mainloop before the required angle is reached. This can be computed by first noting that there will be $\text{INT}(\text{ANGLE}/(\text{PI}/4))$ forty-five degree segments prior to the segment containing the required angle. Furthermore each forty-five segment will contain $\text{RADIUS} * \text{SIN}(\text{PI}/4)$ points as

5. ROM BASIC INTERPRETER

this is the value of the terminating Y coordinate. Therefore the number of points required to reach the start of the segment containing the angle is the product of these two numbers. The total count is produced by adding this figure to the number of points required to cover any remaining angle within the final segment, that is $\text{RADIUS} \times \text{SIN}(\text{REMAINING ANGLE})$ points.

Unfortunately the routine computes the number of points within a segment by linear approximation from the total segment size on the mistaken assumption that successive points subtend equal angles. Thus in the above example the point count computed for the angle is $30/45 \times (80 \times 0.707107) = 37$ instead of the correct value of forty. The error produced by the routine is therefore at a maximum at the centre of each forty-five degree segment and reduces to zero at the end points.

Address... 5D6EH

This is the "DRAW" statement handler. Register pair DE is set to point to the command table at 5D83H and control transfers to the macro language parser (566CH).

Address... 5D83H

This table contains the valid command letters and associated addresses for the "DRAW" statement commands. Those commands which takes a parameter, and consequently have bit 7 set in the table, are shown with an asterisk:

```
CMD TO
ÄÄÄÄÄÄÄÄÄÄÄÄ
U* 5DB1H
D* 5DB4H
L* 5DB9H
R* 5DBCH
M 5DD8H
E* 5DCAH
F* 5DC6H
G* 5DD1H
H* 5DC3H
A* 5E4EH
B 5E46H
N 5E42H
X 5782H
C* 5E87H
S* 5E59H
```

Address... 5DB1H

This is the "DRAW" statement "U" command handler. The operation of the "D", "L", "R", "E", "F", "G" and "H" commands is very similar so no separate description of their handlers is given. The optional numeric parameter is supplied by the macro language parser in register pair DE. This initial parameter is

5. ROM BASIC INTERPRETER

modified by a given handler into a horizontal offset in register pair BC and a vertical offset in register pair DE. For example if leftward or upward movement is required the parameter is negated (5B0BH), if diagonal movement is required the parameter is duplicated so that equal horizontal and vertical offsets are produced. Once the offsets have been prepared control transfers to the line drawing routine (5DFFH).

Address... 5DD8H

This is the "DRAW" statement "M" command handler. The character following the command letter is examined then the two parameters collected from the command string (5719H). If the initial character is "+" or "-" the parameters are regarded as offsets and are scaled (5E66H), rotated through successive ninety degree steps as determined by DRWANG and then added to the current graphics coordinates (5CDCH) to determine the termination point. If DRWFLG shows the "B" mode to be inactive a line is then drawn (5CCDH) from the current graphics coordinates to the termination point. If DRWFLG shows the "N" mode to be inactive the termination coordinates are placed in GRPACX and GRPACY to become the new current graphics coordinates. Finally DRWFLG is zeroed, turning the "B" and "N" modes off, and the handler terminates.

Address... 5E42H

This is the "DRAW" statement "N" command handler, DRWFLG is simply set to 40H.

Address... 5E46H

This is the "DRAW" statement "B" command handler, DRWFLG is simply set to 80H.

Address... 5E4EH

This is the "DRAW" statement "A" command handler. The parameter is checked for magnitude and placed in DRWANG.

Address... 5E59H

This is the "DRAW" statement "S" command handler. The parameter is checked for magnitude and placed in DRWSCL.

Address... 5E66H

This routine is used by the "DRAW" statement "U", "D", "L", "R", "E", "F", "G", "H" and "M" (in offset mode) command handlers to scale the offset supplied in register pair DE by the contents of DRWSCL. Unless DRWSCL is zero, in which case the routine simply terminates, the offset is multiplied using repeated addition and then divided by four (59B4H). To eliminate scaling an "S0" or "S4" command should be used.

5. ROM BASIC INTERPRETER

Address... 5E87H

This is the "DRAW" statement "C" command handler. The parameter is placed in ATRBYT via the SETATR standard routine. There is no check on the MSB of the parameter so illegal values such as "C265" will be accepted without an error message.

Address... 5E91H

This routine is used by the "PAINT" statement handler to check, via the SCALXY standard routine, that the coordinates in register pairs BC and DE are within the screen. If not an "Illegal function call" error is generated (475AH).

Address... 5E9FH

This is the "DIM" statement handler. A return is set up to 5E9AH, so that multiple Arrays can be processed, DIMFLG is made non-zero and control drops into the Variable search routine.

Address... 5EA4H

This is the Variable search routine. On entry register pair HL points to the first character of the Variable name in the program text. On exit register pair HL points to the character following the name and register pair DE to the first byte of the Variable contents in the Variable Storage Area. The first character of the name is taken from the program text, checked to ensure that it is upper case alphabetic (64A7H) and placed in register C. The optional second character, with a default value of zero, is placed in register B, this character may be alphabetic or numeric. Any further alphanumeric characters are then simply skipped over. If a type suffix character ("% ", "\$ ", "! " or "# ") follows the name this is converted to the corresponding type code (2, 3, 4 or 8) and placed in VALTYP. Otherwise the Variable's default type is taken from DEFTBL using the first letter of the name to locate the appropriate entry.

SUBFLG is then checked to determine how any parenthesized subscript following the name should be treated. This flag is normally zero but is modified by the "ERASE" (01H), "FOR" (64H), "FN" (80H) or "DEF FN" (80H) statement handlers to force a particular course of action. In the "ERASE" case control transfers straight to the Array search routine (5FE8H), no parenthesized subscript need be present. In the "FOR", "FN" and "DEF FN" cases control transfers straight to the simple Variable search routine (5F08H), no check is made for a parenthesized subscript. Assuming that the situation is normal the program text is checked for the characters "(" or "[". If either is present control transfers to the Array search routine (5FBAH), otherwise control drops into the simple Variable search routine.

5. ROM BASIC INTERPRETER

otherwise the new Array is added to the end of the existing Array Storage Area. Initialization of the new Array proceeds by storing the two name characters, the type code and the dimensionality (the subscript count) followed by the element count for each dimension. If DIMFLG shows a "DIM" statement to be active the element counts are determined by the subscripts. If the Array is being created by default, with a statement such as "A(1,2,3)=5" for example, a default value of eleven is used. As each element count is stored the total size of the Array is accumulated in register pair DE by successive multiplications (314AH) of the element counts and the element size (the Array type). After a check that this amount of memory is available (6267H) STREND is increased the new area is zeroed and the Array size is stored, in slightly modified form, immediately after the two name characters. Unless the Array is being created by default, in which case the element address must be computed, the routine then terminates.

This is the element address computation point of the Array search routine. The location of a particular element within an Array involves the multiplication (314AH) of subscripts, element counts and element sizes. As there are a variety of ways this could be done the actual method used is best illustrated with an example. The location of element (1,2,3) in a 4*5*6 Array would initially be computed as $((3*5)+2)*4+1$. This is then multiplied by the element size (type) and added to the Array base address to obtain the address of the required element. The computation method is an optimized form which minimizes the number of steps needed, it is equivalent to evaluating $(3*(4*5))+(2*4)+(1)$. The element address is returned in register pair DE.

Address... 60B1H

This is the "PRINT USING" statement handler. Control transfers here from the general "PRINT" statement handler after the applicable output device has been set up. Upon termination control passes back to the general "PRINT" statement exit point (4AFFH) to restore the normal video output. The format string is evaluated (4C65H) and the address and length of the string body obtained from the descriptor. The program text pointer is then temporarily saved. Each character of the format string is examined until one of the possible template characters is found. If the character does not belong in a template it is simply output via the OUTDO standard routine. Once the start of a template is found this is scanned along until a non-template character is found. Control then passes to the numeric output routine (6192H) or the string output routine (6211H).

In either case the program text pointer is restored to register pair HL and the next operand evaluated (4C64H). For numeric output the information gained from the template scan is passed to the numeric conversion routine (3426H) in registers A, B and C and the resulting string displayed (6678H). For

5. ROM BASIC INTERPRETER

string output the required character count is passed to the "LEFT\$" statement handler (6868H) in register C and the resulting string displayed (667BH). For either type of output the program text and format string are then examined to determine whether there are any further characters. If no operands exist the handler terminates. If the format string has been exhausted then it is restarted from the beginning (60BFH), otherwise scanning continues from the current position for the next operand (60f6H).

Address... 6250H

This routine is used by the Interpreter Mainloop and the Variable search routine to move a block of memory upwards. A check is first made to ensure that sufficient memory exists (6267H) and then the block of memory is moved. The top source address is supplied in register pair BC and the top destination address in register pair HL. Copying stops when the contents of register pair BC equal those of register pair DE.

Address... 625EH

This routine is used to check that sufficient memory is available between the top of the Array Storage Area and the base of the Z80 stack. On entry register C contains the number of words the caller requires. If this would narrow the gap to less than two hundred bytes an "Out of memory" error is generated.

Address... 6286H

This is the "NEW" statement handler. TRCFLG, AUTFLG and PTRFLG are zeroed and the zero end link is placed at the start of the Program Text Area. VARTAB is set to point to the byte following the end link and control drops into the run-clear routine.

Address... 629AH

This routine is used by the "NEW", "RUN" and "CLEAR" statement handlers to initialize the Interpreter variables. All interrupts are cleared (636EH) and the default Variable types in DEFTBL set to double precision. RNDX is reset (2C24H) and ONEFLG, ONELIN and OLDTXT are zeroed. MEMSIZ is copied to FRETOP to clear the String Storage Area and DATPTR set to the start of the Program Text Area (63C9H). The contents of VARTAB are copied into ARYTAB and STREND, to clear any Variables, all the I/O buffers are closed (6C1CH) and NLONLY is reset. SAVSTK and the Z80 SP are reset from STKTOP and TEMPPT is reset to the start of TEMPST to clear any string descriptors. The printer is shut down (7304H) and output restored to the screen (4AFFH). Finally PRMLN, NOFUNS, PRMLN2, FUNACT, PRMSTK and SUBFLG are zeroed and the routine terminates.

5. ROM BASIC INTERPRETER

Address... 631BH

This routine is used by the "DEVICE ON" statement handlers to enable an interrupt source, the address of the relevant device's TRPTBI. status byte is supplied in register pair HL. Interrupts are enabled by setting bit 0 of the status byte. Bits 1 and 2 are then examined and, if the device has been stopped and an interrupt has occurred, ONGSBF is incremented (634FH) so that the Runloop will process it at the end of the statement. Finally bit 1 of the status byte is reset to release any existing stop condition.

Address... 632EH

This routine is used by the "DEVICE OFF" statement handlers to disable an interrupt source, the address of the relevant device's TRPTBL status byte is supplied in register pair HL. Bits 0 and 2 are examined to determine whether an interrupt has occurred since the end of the last statement, if so ONGSBF is decremented (6362H) to prevent the Runloop from picking it up. The status byte is then zeroed.

Address... 6331H

This routine is used by the "DEVICE STOP" statement handlers to suspend processing of interrupts from an interrupt source, the address of the relevant device's TRPTBL status byte is supplied in register pair HL. Bits 0 and 2 are examined to determine whether an interrupt has occurred since the end of the last statement, if so ONGSBF is decremented (6362H) to prevent the Runloop from picking it up. Bit 1 of the status byte is then set.

Address... 633EH

This routine is used by the "RETURN" statement handler to release the temporary stop condition imposed during interrupt driven BASIC subroutines, the address of the relevant device's TRPTBL status byte is supplied in register pair HL. Bits 0, and 2 are examined to determine whether a stopped interrupt has occurred since the subroutine was first activated. If so ONGSBF is incremented (634FH) so that the Runloop will pick it up at the end of the statement. Bit 1 of the status byte is then reset. It should be noted that any "DEVICE STOP" Statement within an interrupt driven subroutine will therefore be ineffective.

Address... 6358H

This routine is used by the Runloop interrupt processor (6389H) to clear an interrupt prior to activating the BASIC subroutine, the address of the relevant device's TRPTBL status byte is supplied in register pair HL. ONGSBF is decremented and bit 2 of the status byte is reset.

5. ROM BASIC INTERPRETER

Address... 636EH

This routine is used by the run-clear routine (629AH) to clear all interrupts. The seventy-eight bytes of TRPTBL and the ten bytes of FNKFLG are zeroed.

Address... 6389H

This is the Runloop interrupt processor. ONEFLG is first examined to determine whether an error condition currently exists. If so the routine terminates, no interrupts will be processed until the error clears. CURLIN is then examined and, if the Interpreter is in direct mode, the routine terminates. Assuming all is well a search is made of the twenty-six status bytes in TRPTBL to find the first active interrupt. Note that devices near the start of the table will consequently have a higher priority than those lower down. When the first active status byte is found, that is one with bits 0 and 2 set, the associated address is taken from TRPTBL and placed in register pair DE. The interrupt is then cleared (6358H) and the device stopped (6331H) before control transfers to the "GOSUB" handler (47CFH).

Address... 63C9H

This is the "RESTORE" statement handler. If no line number operand exists DATPTR is set to the start of the Program Storage Area. Otherwise the operand is collected (4769H), the program text searched to find the relevant line (4295H) and its address placed in DATPTR.

Address... 63E3H

This is the "STOP" statement handler. If further text exists in the statement control transfers to the "STOP ON/OFF/STOP" statement handler (77A5H). Otherwise register A is set to 01H and control drops into the "END" statement handler.

Address... 63EAH

This is the "END" statement handler. It is also used, with differing entry points, by the "STOP" statement and for CTRL-STOP and end of text program termination. ONEFLG is first zeroed and then, for the "END" statement only, all I/O buffers are closed (6C1CH). The current program text position is placed in SAVTXT and OLDTXT and the current line number in OLDLIN for use by any subsequent "CONT" statement. The printer is shut down (7304H), a CR LF issued to the screen (7323H) and register pair HL set to point to the "Break" message at 3FDCH. For the "END" statement and end of text cases control then transfers to the Mainloop "OK" point (411EH). For the CTRL-STOP case control transfers to the end of the error handler (40FDH) to display the "Break" message.

5. ROM BASIC INTERPRETER

Address... 6424H

This is the "CONT" statement handler. Unless they are zero, in which case a "Can't CONTINUE" error is generated, the contents of OLDTXT are placed in register pair HL and those of OLDLIN in CURLIN. Control then returns to the Runloop to execute at the old program text position. A program cannot be continued after CTRL-STOP has been used to break from WITHIN a statement, via the CKCNTC standard routine, rather than from between statements.

Address... 6438H

This is the "TRON" statement handler, TRCFLG is simply made non-zero.

Address... 6439H

This is the "TROFF" statement handler, TRCFLG is simply made zero.

Address... 643EH

This is the "SWAP" statement handler. The first Variable is located (5EA4H) and its contents copied to SWPTMP. The location of this Variable and of the end of the Variable Storage Area are temporarily saved. The second Variable is then located (5EA4H) and its type compared with that of the first. If the types fail to match a "Type mismatch" error is generated (406DH). The current end of the Variable Storage Area is then compared with the old end and an "Illegal function call" error generated (475AH) if they differ. Finally the contents of the second Variable are copied to the location of the first Variable (2EF3H) and the contents of SWPTMP to the location of the second Variable (2EF3H).

The checks performed by the handler mean that the second Variable, if it is simple and not an Array, must always be in existence before a "SWAP" Statement is encountered or an error will be generated. The reason for this is that, supposing the first Variable was an Array, then the creation of a second (simple) Variable would move the Array Storage Area upwards invalidating its saved location. Note that the perfectly legal case of a simple first Variable and a newly created simple second Variable is also rejected.

Address... 6477H

This is the "ERASE" statement handler. SUBFLG is first set to 01H, to control the Variable search routine, and the Array located (5EA4H). All the following Arrays are moved downward and STREND set to its new, lower value. The program text is then checked and, if a comma follows, control transfers back to the start of the handler.

5. ROM BASIC INTERPRETER

Address... 64A7H

This routine checks whether the character whose address is supplied in register pair HL is upper case alphabetic, if so it returns Flag NC.

Address... 64AFH

This is the "CLEAR" statement handler. If no operands are present control transfers to the run-clear routine (62A1H) to remove all current Variables. Otherwise the string space operand is evaluated (4756H) followed by the optional top of memory operand (542FH). The top of memory value is checked and an "Illegal function call" error generated (475AH) if it is less than 8000H or greater than F380H. The space required by the I/O buffers (267 bytes each) and the String Storage Area is subtracted from the top of memory value and an "Out of memory" error generated (6275H) if there is less than 160 bytes remaining to the base of the Variable Storage Area. Assuming all is well HIMEM, MEMSIZ and STKTOP are set to their new values and the remaining storage pointers reset via the run-clear routine (62A1H). The I/O buffer storage is re-allocated (7E6BH) and the handler terminates.

Unfortunately the computation of MEMSIZ and STKTOP, when a new top of memory is specified, is incorrect resulting in the top of the String Storage Area being set one byte too high. This can be seen with the following where an illegal string is accepted:

```
10 CLEAR 200,&HF380
20 A$=STRING$(201,"A")
30 PRINT FRE(" ")
```

Because there should be an extra DEC HL instruction at 64EBH the new values of MEMSIZ and STKTOP are initially set one byte too high. When the run-clear routine is called MEMSIZ is copied into FRETOP, the top of the String Storage Area, which results in this being one byte too high as well. Although MEMSIZ and STKTOP are correctly recomputed when the file pointers are reset, FRETOP is left with its incorrect value. When the "FRE" statement is executed in line thirty, and string garbage collection initiated, FRETOP is restored to its correct value but, because the string overflows the String Storage Area by one byte, the amount of free space displayed is -1 byte. To correctly set all the system pointers any alteration of the top of memory should be followed immediately by another "CLEAR" statement with no operands.

Address... 6520H

This routine computes the difference between the contents of register pairs HL and DE. It is a duplicate of the short section of code from 64ECH to 64F1H and is completely unused.

5. ROM BASIC INTERPRETER

Address... 6527H

This is the "NEXT" statement handler. Assuming further text is present in the statement the loop Variable is located (5EA4H), otherwise a default address of zero is taken. The stack is then searched for the corresponding "FOR" parameter block (3FE2H). If no parameter block is found, or if a "GOSUB" parameter block is found first, a "NEXT without FOR" error is generated (405BH). Assuming the parameter block is found the intervening section of stack, together with any "FOR" blocks it may contain, is discarded. The loop Variable type is then taken from the parameter block and examined to determine the precision required during subsequent operations.

The STEP value is taken from the parameter block and added (3172H, 324EH or 2697H) to the current contents of the loop Variable which is then updated. The new value is compared (2F4DH, 2F21H or 2F5CH) with the termination value from the parameter block to determine whether the loop has terminated (65B6H). The loop will terminate for a positive STEP if the new loop value is GREATER than the termination value. The loop will terminate for a negative step if the new loop value is LESS than the termination value. If the loop has not terminated the original program text position and line number are taken from the parameter block and control transfers to the Runloop (45FDH). If the loop has terminated the parameter block is discarded from the stack and, unless further program text is present in which control transfers back to the start of the handler, control transfers to the Runloop to execute the next statement (4601H).

Address... 65C8H

This routine is used by the Expression Evaluator to find the relation (<>=) between two string operands. The address of the first string descriptor is supplied on the Z80 stack and the address of the second in DAC. The result is returned in register A and the flags as for the numeric relation routines:

```
String 1=String 2 ... A=00H, Flag Z,NC
String 1<String 2 ... A=01H, Flag NZ,NC
String 1>String 2 ... A=FFH, Flag NZ,C
```

Comparison commences at the first character of each string and continues until the two characters differ or one of the strings is exhausted. Control then returns to the Expression Evaluator (4F57H) to place the true or false numeric result in DAC.

Address... 65F5H

This routine is used by the Factor Evaluator to apply the "OCT\$" function to an operand contained in DAC. The number is first converted to textual form in FBUFFR (371EH) and then the result string is created (6607H).

5. ROM BASIC INTERPRETER

Address... 65FAH

This routine is used by the Factor Evaluator to apply the "HEX\$" function to an operand contained in DAC. The number is first converted to textual form in FBUFFR (3722H) and then the result string is created (6607H).

Address... 65FFH

This routine is used by the Factor Evaluator to apply the "BIN\$" function to an operand contained in DAC. The number is first converted to textual form in FBUFFR (371AH) and then the result string is created (6607H).

Address... 6604H

This routine is used by the Factor Evaluator to apply the "STR\$" function to an operand contained in DAC. The number is first converted to textual form in FBUFFR (3425H) then analyzed to determine its length and address (6635H). After checking that sufficient space is available (668EH) the string is copied to the String Storage Area (67C7H) and the result descriptor created (6654H).

Address... 6627H

This routine first checks that there is sufficient space in the String Storage Area for the string whose length is supplied in register A (668EH). The string length and the address where the string will be placed in the String Storage Area are then copied to DSCTMP.

Address... 6636H

This routine is used by the Factor Evaluator to analyze the character string whose address is supplied in register pair HL. The character string is scanned until a terminating character (00H or ") is found. The length and starting address are then placed in DSCTMP (662AH) and control drops into the descriptor creation routine.

Address... 6654H

This routine is used by the string functions to create a result descriptor. The descriptor is copied from DSCTMP to the next available position in TEMPST and its address placed in DAC. Unless TEMPST is full, in which case a "String formula too complex" error is generated, TEMPPT is increased by three bytes and the routine terminates.

Address... 6678H

This routine displays the message, or string, whose address is supplied in register pair HL. The string is analyzed (6635H)

5. ROM BASIC INTERPRETER

and its storage freed (67D3H). Successive characters are then taken from the string and displayed, via the OUTDO standard routine, until the string is exhausted.

Address... 668EH

This routine checks that there is room in the String Storage Area to add the string whose length is supplied in register A. On exit register pair DE points to the starting address in the String Storage Area where the string should be placed. The length of the string is first subtracted from the current free location contained in FRETOP. This is then compared with STKTOP, the lowest allowable location for string storage, to determine whether there is space for the string. If so FRETOP is updated with the new position and the routine terminates. If there is insufficient space for the string then garbage collection is initiated (66B6H) to try and eliminate any dead strings. If, after garbage collection, there is still not enough space an "Out of string space" error is generated.

Address... 66B6H

This is the string garbage collector, its function is to eliminate any dead strings from the String Storage Area. The basic problem with string Variables, as opposed to numeric ones, is that their lengths vary. If string bodies were stored with their Variables in the Variable Storage Area even such apparently simple statements as A\$=A\$+"X" would require the movement of thousands of bytes of memory and slow execution speeds dramatically. The method used by the Interpreter to overcome this problem is to keep the string bodies separate from the Variables. Thus strings are kept in the String Storage Area and each Variable holds a three byte descriptor containing the length and address of the associated string. Whenever a string is assigned to a Variable it is simply added to the heap of existing strings in the String Storage Area and the Variable's descriptor changed. No attempt is made to eliminate any previous string belonging to the Variable, by restructuring the heap, as this would wipe out any throughput gains.

If sufficient Variable assignments are made it is inevitable that the String Storage Area will fill up. In a typical program many of these strings will be unused, that is the result of previous assignments. Garbage collection is the process whereby these dead strings are removed. Every string Variable in memory, including Arrays and the local Variables present during evaluation of user defined functions, is examined until the one is found whose string is stored highest in the heap. This string is then moved to the top of the String Storage Area and the Variable contents modified to point to the new location. The owner of the next highest string is then found and the process repeated until every string belonging to a Variable has been compacted.

5. ROM BASIC INTERPRETER

If a large number of Variables are present garbage collection may take an appreciable time. The process can be seen at work with the following program which repeatedly assigns the string "AAAA" to each element of the Array A\$. The program will run at full speed for the first two hundred and fifty assignments and then pause to eliminate the fifty dead strings. A further fifty assignments can then be made before a further garbage collection is required:

```
10 CLEAR 1000
20 DIM A$(200)
30 FOR N=0 TO 200
40 A$(N)=STRING$(4,"A")
50 PRINT". ";
60 NEXT N
70 GOTO 30
```

The String Storage Area is also used to hold the intermediate strings produced during expression evaluation. Because so many string functions take multiple arguments, "MID\$" takes three for example, the management of intermediate results is a major problem. To deal with it a standardized approach to string results is taken throughout the Interpreter. A producer of a string simply adds the string body to the heap in the String Storage Area, adds the descriptor to the descriptor heap in TEMPST and places the address of the descriptor in DAC. It is up to the user of the result to free this storage (67D0H) once it has processed the string. This rule applies to all parts of the system, from the individual function handlers back through the Expression Evaluator to the statement handlers, with only two exceptions.

The first exception occurs when the Factor Evaluator finds an explicitly stated string, such as "SOMETHING" in the program text. In this case it is not necessary to copy the string to the String Storage Area as the original will suffice.

The second exception occurs when the Factor Evaluator finds a reference to a Variable. In this case it is not necessary to place a copy of the descriptor in TEMPST as one already exists inside the Variable.

Address... 6787H

This routine is used by the Expression Evaluator to concatenate two string operands. Control transfers here when a "+" token is found following a string operand so the first action taken is to fetch the second string operand via the Factor Evaluator (4DC7H). The lengths are then taken from both string descriptors and added together to check the length of the combined string. If this is greater than two hundred and fifty-five characters a "String too long" error is generated. After checking that space is available in the String Storage Area (6627H) the storage of both operands is freed (67D6H). The first string is then copied to the String Storage Area (67BFH)

5. ROM BASIC INTERPRETER

and followed by the second one (67BFH). The result descriptor is created (6654H) and control transfers back to the Expression Evaluator (4C73H)'

Address... 67D0H

This routine frees any storage occupied by the string whose descriptor address is contained in DAC. The address of the descriptor is taken from DAC and examined to determine whether it is that of the last descriptor in TEMPST (67EEH), if not the routine terminates. Otherwise TEMPPT is reduced by three bytes clearing this descriptor from TEMPST. The address of the string body is then taken from the descriptor and compared with FRETOP to see if this is the lowest string in the String Storage Area, if not the routine terminates. Otherwise the length of the string is added to FRETOP, which is then updated with this new value, freeing the storage occupied by the string body.

Address... 67FFH

This routine is used by the Factor Evaluator to apply the "LEN" function to an operand contained in DAC. The operand's storage is freed (67D0H) and the string length taken from the descriptor and placed in DAC as an integer (4FCFH).

Address... 680BH

This routine is used by the Factor Evaluator to apply the "ASC" function to an operand contained in DAC. The operand's storage is freed and the string length examined (6803H), if it is zero an "Illegal function call" error is generated (475AH). Otherwise the first character is taken from the string and placed in DAC as an integer (4FCFH).

Address... 681BH

This routine is used by the Factor Evaluator to apply the "CHR\$" function to an operand contained in DAC. After checking that sufficient space is available (6625H) the operand is converted to a single byte integer (521FH). This character is then placed in the String Storage Area and the result descriptor created (6654H).

Address... 6829H

This routine is used by the Factor Evaluator to apply the "STRING\$" function. After checking for the open parenthesis character the length operand is evaluated and placed in register E (521CH). The second operand is then evaluated (4C64H). If it is numeric it is converted to a single byte integer (521FH) and placed in register A. If it is a string the first character is taken from it and placed in register A (680FH). Control then drops into the "SPACE\$" function to create the result string.

5. ROM BASIC INTERPRETER

Address... 6848H

This routine is used by the Factor Evaluator to apply the "SPACE\$" function to an operand contained in DAC. The operand is first converted to a single byte integer in register E (521FH). After checking that sufficient space is available (6627H) the required number of spaces are copied to the String Storage Area and the result descriptor created (6654H).

Address... 6861H

This routine is used by the Factor Evaluator to apply the "LEFT\$" function. The first operand's descriptor address and the integer second operand are supplied on the Z80 stack. The slice size is taken from the stack (68E3H) and compared to the source string length. If the source string length is less than the slice size it replaces it as the length to extract. After checking that sufficient space is available (668EH) the required number of characters are copied from the start of the source string to the String Storage Area (67C7H). The source string's storage is then freed (67D7H) and the result descriptor created (6654H).

Address... 6891H

This routine is used by the Factor Evaluator to apply the "RIGHT\$" function. The first operand's descriptor address and the integer second operand are supplied on the Z80 stack. The slice size is taken from the stack (68E3H) and subtracted from the source string length to determine the slice starting position. Control then transfers to the "LEFT\$" routine to extract the slice (6865H).

Address... 689AH

This routine is used by the Factor Evaluator to apply the "MID\$" function. The first operand's descriptor address and the integer second operand are supplied on the Z80 stack. The starting position is taken from the stack (68E6H) and checked, if it is zero an "Illegal function call" error is generated (475AH). The optional slice size is then evaluated (69E4H) and control transfers to the "LEFT\$" routine to extract the slice (6869H).

Address... 68BBH

This routine is used by the Factor Evaluator to apply the "VAL" function to an operand contained in DAC. The string length is taken from the descriptor (6803H) and checked, if it is zero it is placed in DAC as an integer (4FCFH). The length is then added to the starting address of the string body to give the location of the character immediately following it. This is temporarily replaced with a zero byte and the string is converted to numeric form in DAC (3299H). The original

5. ROM BASIC INTERPRETER

character is then restored and the routine terminates. The temporary zero byte delimiter is necessary because strings are packed together in the String Storage Area, without it the numeric converter would run on into succeeding strings.

Address... 68E3H

This routine is used by the "LEFT\$", "MID\$" and "RIGHT\$" function handlers to check that the next program text character is ")" and then to pop an operand from the Z80 stack into register pair DE.

Address... 68EBH

This routine is used by the Factor Evaluator to apply the "INSTR" function. The first operand, which may be the starting position or the source string, is evaluated (4C62H) and its type tested. If it is the source string a default starting position of one is taken. If it is the starting position operand its value is checked and the source string operand evaluated (4C64H). The pattern string is then evaluated (4C64H) and the storage of both operands freed (67D0H). The length of the pattern string is checked and, if zero, the starting position is placed in DAC (4FCFH). The pattern string is then checked against successive characters from the source string, commencing at the starting position, until a match is found or the source string is exhausted. With a successful search the character position of the substring is placed in DAC as an integer (4FCFH), otherwise a zero result is returned.

Address... 696EH

This is the "MID\$" statement handler. After checking for the open parenthesis character the destination Variable is located (5EA4H) and checked to ensure that it is a string type (3058H). The address of the string body is then taken from the Variable and examined to determine whether it is inside the Program Text Area, as would be the case for an explicitly stated string. If this is the case the string body is copied to the String Storage Area (6611H) and a new descriptor copied to the Variable (2EF3H). This is done to avoid modifying the program text. The starting position is then evaluated (521CH) and checked, if it is zero an "Illegal function call" error is generated (475AH). The optional slice length operand is evaluated (69E4H) followed by the replacement string (4C5FH) whose storage is then freed (67D0H). Characters are then copied from the replacement string to the destination string until either the slice length is completed or the replacement string is exhausted.

Address... 69E4H

This routine is used by various string functions to evaluate an optional operand (521CH) and return the result in register

5. ROM BASIC INTERPRETER

E. If no operand is present a default value of 255 is returned.

Address... 69F2H

This routine is used by the Factor Evaluator to apply the "FRE" function to an operand contained in DAC. If the operand is numeric the single precision difference between the Z80 Stack Pointer and the contents of STREND is placed in DAC (4FC1H). If the operand is a string type its storage is freed (67D3H) and garbage collection initiated (66B6H). The single precision difference between the contents of FRETOP and those of STKTOP is then placed in DAC (4FC1H).

Address... 6A0EH

This routine is used by the file I/O handlers to analyze a filespec such as "A:FILENAME.BAS". The filespec consists of three parts, the device, the filename and the type extension. On entry register pair HL points to the start of the filespec in the program text. On exit register D holds the device code, the filename is in positions zero to seven of FILNAM and the type extension in positions eight to ten. Any unused positions are filled with spaces.

The filespec string is evaluated (4C64H) and its storage freed (67D0H), if the string is of zero length a "Bad file name" error is generated (6E6BH). The device name is parsed (6F15H) and successive characters taken from the filespec and placed in FILNAM until the string is exhausted, a "." character is found or FILNAM is full. A "Bad file name" error is generated (6E6BH) if the filespec contains any control characters, that is those whose value is smaller than 20H. If the filespec contains a type extension a "Bad file name" error is generated (6E6BH) if it is longer than three characters or if the filename is longer than eight characters. If no type extension is present the filename may be any length, extra characters are simply ignored.

Address... 6A6DH

This routine is used by the file I/O handlers to locate the I/O buffer FCB whose number is supplied in register A. The buffer number is first checked against MAXFIL and a "Bad file number" error generated (6E7DH) if it is too large. Otherwise the required address is taken from the file pointer block and placed in register pair HL and the buffer's mode taken from byte 0 of the FCB and placed in register A.

Address... 6A9EH

This routine is used by the file I/O handlers to evaluate an I/O buffer number and to locate its FCB. Any "#" character is skipped (4666H) and the buffer number evaluated (521CH). The FCB is located (6A6DH) and a "File not open" error generated

5. ROM BASIC INTERPRETER

(6E77H) if the buffer mode byte is zero. Otherwise the FCB address is placed in PTRFIL to redirect the Interpreter's output.

Address... 6AB7H

This is the "OPEN" statement handler. The filespec is analyzed (6A0EH) and any following mode converted to the corresponding mode byte, these are: "FOR INPUT" (01H), "FOR OUTPUT" (02H) and "FOR APPEND" (08H). If no mode is explicitly stated random mode (04H) is assumed. The "AS"- characters are checked and the buffer number evaluated (521CH), if this is zero a "Bad file number" error is generated (6E7DH). The FCB is then located (6A6DH) and a "File already open" error generated (6E6EH) if the buffer's mode byte is anything other than zero. The device code is placed in byte 4 of the FCB, the open function dispatched (6F8FH) and the Interpreter's output reset to the screen (4AFFH).

Address... 6B24H

This routine is used by the file I/O handlers to close the I/O buffer whose number is supplied in register A. The FCB is located (6A6DH) and, provided the buffer is in use, the close function dispatched (6F8FH) and the buffer filled with zeroes (6CEAH). PTRFIL and the FCB mode byte are then zeroed to reset the Interpreter's output to the screen.

Address... 6B5BH

This is the "LOAD", "MERGE" and "RUN filespec" statement handler. The filespec is analyzed (6A0EH) and then, for "LOAD" and "RUN" only, the program text examined to determine whether the auto-run "R" option is specified. I/O buffer 0 is opened for input (6AFAH) and the first byte of FILNAM set to FFH if auto-run is required. For "LOAD" and "RUN" only any program text is then cleared via the "NEW" statement handler (6287H). As this will reset the Interpreter's output to the screen the buffer FCB is again located and placed in PTRFIL (6AAAH). Control then transfers directly to the Interpreter Mainloop (4134H) for the program text to be loaded as if typed from the keyboard. Note that no error checking of any sort is carried out on the data read.

Address... 6BA3H

This is the "SAVE" statement handler. The filespec is analyzed (6A0EH) and the program text examined to determine whether the ASCII "A" suffix is present. This is only relevant under Disk BASIC, it makes no difference on a standard MSX machine. I/O buffer 0 is opened for output (6AFAH) and control transfers to the "LIST" statement handler (522EH) to output the program text. Note that no error checking information of any sort accompanies the text.

5. ROM BASIC INTERPRETER

Address... 6BDAH

This routine is used by the file I/O handlers to return the device code for the currently active I/O buffer. The FCB address is taken from PTRFIL then the device code taken from byte 4 of the FCB and placed in register A.

Address... 6BE7H

This routine is used by the file I/O handlers to perform an operation on a number of I/O buffers. The address of the relevant routine is supplied in register pair BC and the buffer count in register A. For example if register pair BC contained 6B24H and register A contained 03H buffers 3, 2, 1 and 0 would be closed. The routine has a slightly different function if it is entered with FLAG NZ. In this case the I/O buffer numbers are taken sequentially from the program text and evaluated (521CH) before the operation is performed, a typical case might be "#1,#2".

Address... 6C14H

This is the "CLOSE" statement handler. Register pair BC is set to 6B24H, register A is loaded with the contents of MAXFIL and the required number of buffers closed (6BE7H).

Address... 6C1CH

This routine is used by the file I/O handlers to close every I/O buffer. Register pair BC is set to 6B24H, register A is loaded with the contents of MAXFIL and all buffers closed (6BE7H).

Address... 6C2AH

This is the "LFILES" statement handler. PRTFLG is made non-zero, to direct output to the printer, and control drops into the "FILES" statement handler.

Address... 6C2FH

This is the "FILES" statement handler, an "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 6C35H

Control transfers here from the general "PUT" and "GET" handlers (7758H) when the program text contains anything other than a "SPRITE" token. A "Sequential I/O only" error is generated (6E86H) on a standard MSX machine.

Address... 6C48H

This routine is used by the file I/O handlers to

5. ROM BASIC INTERPRETER

sequentially output the character supplied in register A. The character is placed in register C and the sequential output function dispatched (6F8FH).

Address... 6C71H

This routine is used by the file I/O handlers to sequentially input a single character. The sequential input function is dispatched (6F8FH) and the character returned in register A, FLAG C indicates an EOF (End Of File) condition.

Address... 6C87H

This routine is used by the Factor Evaluator to apply the "INPUT\$" function. The program text is checked for the "\$" and "(" characters and the length operand evaluated (521CH). If an I/O buffer number is present it is evaluated, the FCB located (6A9EH) and the mode byte examined. An "Input past end" error is generated (6E83H) if the buffer is not in input or random mode. After checking that sufficient space is available (6627H) the required number of characters are sequentially input (6C71H), or collected via the CHGET standard routine, and copied to the String Storage Area. Finally the result descriptor is created (6654H).

Address... 6CEAH

This routine is used by the file I/O handlers to fill the buffer whose FCB address is contained in PTRFIL with two hundred and fifty-six zeroes.

Address... 6CFBH

This routine is used by the file I/O handlers to return, in register pair HL, the starting address of the buffer whose FCB address is contained in PTRFIL. This just involves adding nine to the FCB address.

Address... 6D03H

This routine is used by the Factor Evaluator to apply the "LOC" function to the I/O buffer whose number is contained in DAC. The FCB is located (6A6AH) and the LOC function dispatched (6F8FH). An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 6D14H

This routine is used by the Factor Evaluator to apply the "LOF" function to the I/O buffer whose number is contained in DAC. The FCB is located (6A6AH) and the LOF function dispatched (6F8FH). An "Illegal function call" error is generated (475AH) on a standard MSX machine.

5. ROM BASIC INTERPRETER

Address... 6D25H

This routine is used by the Factor Evaluator to apply the "EOF" function to the I/O buffer whose number is contained in DAC. The FCB is located (6A6AH) and the EOF function dispatched (6F8FH).

Address... 6D39H

This routine is used by the Factor Evaluator to apply the "FPOS" function to the I/O buffer whose number is contained in DAC. The FCB is located (6A6AH) and the FPOS function dispatched (6F8FH). An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 6D48H

Control transfers to this routine when the Interpreter Mainloop encounters a direct statement, that is one with no line number. The ISFLIO standard routine is first used to determine whether a "LOAD" statement is active. If input is coming from the keyboard control transfers to the Runloop execution point (4640H) to execute the statement. If input is coming from the cassette buffer 0 is closed (6B24H) and a "Direct statement in file" error generated (6E71H). This could happen on a standard MSX machine either through a cassette error or by attempting to load a text file with no line numbers.

Address... 6D57H

This routine is used by the "INPUT", "LINE INPUT" and "PRINT" statement handlers to check for the presence of a "#" character in the program text. If one is found the I/O buffer number is evaluated (521BH), the FCB located and its address placed in PTRFIL (6AAAH). The mode byte of the FCB is then compared with the mode number supplied by the statement handler in register C, if they do not match a "Bad file number" error is generated (6E7DH). With "PRINT" the allowable modes are output, random and append. With "INPUT" and "LINE INPUT" the allowable modes are input and random. Note that on a standard MSX machine not all these modes are supported at lower levels. Some sort of error will consequently be generated at a later stage for illegal modes.

Address... 6D83H

This routine is used by the "INPUT" statement handler to input a string from an I/O buffer. A return is first set up to the "READ/INPUT" statement handler (4BF1H). The characters which delimit the input string, comma and space for a numeric Variable and comma only for a string Variable, are placed in registers D and E and control transfers to the "LINE INPUT" routine (6DA3H).

5. ROM BASIC INTERPRETER

Address... 6D8FH

This is the "LINE INPUT" statement handler when input is from an I/O buffer. The buffer number is evaluated, the FCB located and the mode checked (6D55H). The Variable to assign to is then located (5EA4H) and its type checked to ensure it is a string type (3058H). A return is set up to the "LET" statement handler (487BH) to perform the assignment and the input string collected.

Characters are sequentially input (6C71H) and placed in BUF until the correct delimiter is found, EOF is reached or BUF fills up (6E41H). When the terminating condition is reached and assignment is to a numeric Variable the string is converted to numeric form in DAC (3299H). When assignment is to a string Variable the string is analyzed and the result descriptor created (6638H).

For "LINE INPUT" all characters are accepted until a CR code is reached. Note that if this CR code is preceded by a LF code then it will not function as a delimiter but will merely be accepted as part of the string. For "INPUT" to a numeric Variable leading spaces are stripped then characters accepted until a CR code, a space or a comma is reached. Note that as for "LINE INPUT" a CR code will not function as a delimiter when preceded by a LF code. In this case however the CR code will not be placed in BUF but ignored. For "INPUT" to a string Variable leading spaces are stripped then characters accepted until a CR or comma is reached. Note that as for "LINE INPUT" a CR code will not function as a delimiter when preceded by a LF code. In this case however neither code will be placed in BUF both are ignored. An alternative mode is entered when the first character read, after any spaces, is a double quote character. In this case all characters will be accepted, and stored in BUF, until another double quote delimiter is read.

Once the input string has been accepted the terminating delimiter is examined to see if any special action is required with respect to trailing characters. If the input string was delimited by a double quote character or a space then any succeeding spaces will be read in and ignored until a non-space character is found. If this character is a comma or CR code then it is accepted and ignored. Otherwise a putback function is dispatched (6F8FH) to return the character to the I/O buffer. If the input string was delimited by a CR code then the next character is read in and checked. If this is a LF code it will be accepted but ignored. If it is not a LF code then a putback function is dispatched (6F8FH) to return the character to the I/O buffer.

Address... 6E6BH

This is a group of ten file I/O related error generators. Register E is loaded with the relevant error code and control

5. ROM BASIC INTERPRETER

transfers to the error handler (406FH):

```
ADDR. ERROR
AAAAAAAAAAAAAAAAAAAAAAAAAAAA
6E6BH Bad file name
6E6EH File already open
6E71H Direct statement in file
6E74H File not found
6E77H File not open
6E7AH Field overflow
6E7DH Bad file number
6E80H Internal error
6E83H Input past end
6E86H Sequential I/O only
```

Address... 6E92H

This is the "BSAVE" statement handler. The filespec is analyzed (6A0EH) and the start address evaluated (6F0BH). The stop address is then evaluated (6F0BH) and placed in SAVEND followed by the optional entry address (6F0BH) which is placed in SAVENT. If no entry address exists the start address is taken instead. The device code is checked to ensure that it is CAS, if not a "Bad file name" error is generated (6E6BH), and the data written to cassette (6FD7H). Note that no buffering is involved, data is written directly to the cassette, and no error checking information accompanies the data.

Address... 6EC6H

This is the "BLOAD" statement handler. The filespec is analyzed (6A0EH) and RUNBNF made non-zero if the auto-run "R" option is present in the program text. The optional load offset, with a default value of zero, is then evaluated (6F0BH) and the device code checked to ensure that it is CAS, if not a "Bad file name" error is generated (6E6BH). Data is then read directly from cassette (7014H), as with "BSAVE" no buffering or error checking is involved.

Address... 6EF4H

Control transfers to this routine when the "BLOAD" statement handler has completed loading data into memory. If RUNBNF is zero buffer 0 is closed (6B24H) and control returns to the Runloop. Otherwise buffer 0 is closed (6B24H), a return address of 6CF3H is set up (this routine just pops the program text pointer back into register pair HL and returns to the Runloop) and control transfers to the address contained in SAVENT.

Address... 6F0BH

This routine is used by the "BLOAD" and "BSAVE" handlers to evaluate an address operand, the result is returned in register pair DE. The operand is evaluated (4C64H) then converted to an

5. ROM BASIC INTERPRETER

integer (5439H).

Address... 6F15H

This routine is used by the filespec analyzer to parse a device name such as "CAS:". On entry register pair HL points to the start of the filespec string and register E contains its length. If no device name is present the default device code (CAS=FFH) is returned in register A with FLAG Z. If a legal device name is present its code is returned in register A with FLAG NZ.

The filespec is examined until a ":" character is found then the name compared with each of the legal device names in the device table at 6F76H. If a match is found the device code is taken from the table and returned in register A. If no match is found control transfers to the external ROM search routine (55F8H). Note that any lower case characters are turned to upper case for comparison purposes. Thus crt and CRT, for example, are the same device.

Address... 6F76H

This table is used by the device name parser, it contains the four device names and codes available on a standard MSX machine:

CAS ... FFH LPT ... FEH CRT ... FDH GRP ... FCH

Address... 6F87H

This table is used by the function dispatcher (6F8FH), it contains the address of the function decoding table for each of the four standard MSX devices:

CAS ... 71C7H LPT ... 72A6H CRT ... 71A2H GRP ... 7182H

Address... 6F8FH

This is the file I/O function dispatcher. In conjunction with the Interpreter's buffer structure it provides a consistent, device independent method of inputting or outputting data. The required function code is supplied in register A and the address of the buffer FCB in register pair HL.

The device code is taken from byte 4 of the FCB and examined to determine whether it is one of the four standard devices, if not control transfers to the external ROM function dispatcher (564AH). Otherwise the address of the device's function decoding table is taken from the table at 6F87H, the required function's address taken from it and control transferred to the relevant function handler.

5. ROM BASIC INTERPRETER

Address... 6FB7H

This is the "CSAVE" statement handler. The filename is evaluated (7098H) followed by the optional baud rate operand (7A2DH). The identification block is then written to cassette (7125H) with a filetype byte of D3H. The contents of the Program Text Area are written directly to cassette as a single data block (713EH). Note that no error checking information accompanies the data.

Address... 6FD7H

Control transfers to this routine from the "BSAVE" statement handler to write a block of memory to cassette. The identification block is first written to cassette (7125H) with a filetype byte of D0H. The motor is then turned on and a short header written to cassette (72F8H). The starting address is popped from the Z80 stack and written to cassette LSB first, MSB second (7003H). The stop address is taken from SAVEND and written to cassette LSB first, MSB second (7003H). The entry address is taken from SAVENT and written to cassette LSB first, MSB second (7003H). The required area of memory is then written to cassette one byte at a time (72DEH) and the cassette motor turned off via the TAPOOF standard routine. Note that no error checking information accompanies the data.

Address... 7003H

This routine writes the contents of register pair HL to cassette with register L first (72DEH) and register H second (72DEH).

Address... 700BH

This routine reads two bytes from cassette and places the first in register L (72D4H), the second in register H (72D4H).

Address... 7014H

Control transfers to this routine from the "BLOAD" statement handler to load data from the cassette into memory. The cassette is read until an identification block with a file type of D0H and the correct filename is found (70B8H). The data block header is then located on the cassette (72E9H). The offset value is popped from the Z80 stack and added to the start address from the cassette (700BH). The stop address is read from cassette (700BH) and the offset added to this as well. The entry address is read from cassette (700BH) and placed in SAVENT in case auto-run is required. Successive data bytes are then read from cassette (72D4H) and placed in memory, at the start address initially, until the stop address is reached. Finally the motor is turned off via the TAPIOF standard routine and control transfers to the "BLOAD" termination point (6EF4H).

5. ROM BASIC INTERPRETER

Address... 703FH

This is the "CLOAD" and "CLOAD?" statement handler. The program text is first checked for a trailing "PRINT" token (91H) which is how the "?" character is tokenized. The filename is then evaluated (708CH) and the cassette read until an identification block with a filetype of D3H and the correct filename is found (70B8H). For "CLOAD" a "NEW" operation is then performed (6287H) to erase the current program text. For "CLOAD?" all pointers in the Program Text Area are converted to line numbers (54EAH) to match the cassette data.

The data block header is located on the cassette and successive data bytes read from cassette and placed in memory or compared with the current memory contents (715DH). When the data block has been completely read the message "OK" is displayed (6678H) and control transfers directly to the end of the Interpreter Mainloop (4237H) to reset the Variable storage pointers. For "CLOAD?" reading of the data block will terminate if the cassette byte is not the same as the program text byte in memory. If the address where this occurred is above the end of the Program Text Area then the handler terminates with an "OK" message as before. Otherwise a "Verify error" is generated.

Address... 708CH

This routine is used by the "CLOAD" and "CSAVE" statement handlers to evaluate a filename in the program text. The two handlers use different entry points so that a null filename is allowed for "CLOAD" but not for "CSAVE". The filename string is evaluated (4C64H), its storage freed (680FH) and the first six characters copied to FILNAM. If the filename is longer than six characters the excess is ignored. If the filename is shorter than six characters then FILNAM is padded with spaces.

Address... 70B8H

This routine is used by the "CLOAD" and "BLOAD" statement handlers and for the dispatcher open function (when the device is CAS and the mode is input) to locate an identification block on the cassette. On entry the filename is in FILNAM and the file type in register C, D3H for a tokenized BASIC (CLOAD) file, D0H for a binary (BLOAD) file and EAH for an ASCII (LOAD or data) file.

The cassette motor is turned on and the cassette read until a header is found (72E9H). Each identification block is prefixed by ten file type characters so successive characters are read from cassette (72D4H) and compared to the required file type. If the file type characters do not match control transfers back to the start of the routine to find the next header. Otherwise the next six characters are read in (72D4H) and placed in FILNAM. If FILNAM is full of spaces no filename

5. ROM BASIC INTERPRETER

match is attempted and the identification block has been found. Otherwise the contents of FILNAM and FILNM2 are compared to determine whether this is the required file. If the match is unsuccessful, and the Interpreter is in direct mode, the message "Skip:" is displayed (710DH) followed by the filename. Control then transfers back to the start of the routine to try the next header. If the match is successful, and the Interpreter is in direct mode, the message "Found:" is displayed (710DH) followed by the filename and the routine terminates.

Address... 70FFH

This is the plain text message "Found:" terminated by a zero byte.

Address... 7106H

This is the plain text message "Skip :" terminated by a zero byte.

Address... 710DH

Unless CURLIN shows the Interpreter to be in program mode this routine first displays (6678H) the message whose address is supplied in register pair HL, followed by the six characters contained in FILENAM2.

Address... 7125H

This routine is used by the "CSAVE" and "BSAVE" statement handlers and for the dispatcher open function (when the device is CAS and the mode is output) to write an identification block to cassette. On entry the filename is in FILNAM and the filetype in register A, D3H for a tokenized BASIC (CSAVE) file, DOH for a binary (BSAVE) file and EAH for an ASCII (SAVE or data) file. The cassette motor is turned on and a long header written to cassette (72F8H) The filetype byte is then written to cassette (72DEH) ten times followed by the first six characters from FILNAM (72DEH). The cassette motor is turned off via the TAPOOF standard routine and the routine terminates.

Address... 713EH

This routine is used by the "CSAVE" statement handler to write the Program Text Area to cassette as a single data block. All pointers in the program text are converted back to line numbers (54EAH) to make the text address independent. The cassette motor is turned on and a short header written to cassette (72F8H) The entire Program Text Area is then written to cassette a byte at a time (72DEH) and followed with seven zero bytes (72DEH) as a terminator. The cassette motor is then turned off via the TAPOOF standard routine and the routine terminates.

5. ROM BASIC INTERPRETER

Address... 715DH

This routine is used by the "CLOAD" and "CLOAD?" statement handlers to read a single data block into the Program Text Area or to compare it with the current contents. On entry register A contains a flag to distinguish between the two statements, 00H for "CLOAD" and FFH for "CLOAD?". The cassette motor is turned on and the first header located (72E9H). Successive characters are read from cassette (72D4H) and placed in the Program Text Area or compared with the current contents. If the current statement is "CLOAD?" the routine will terminate with FLAG NZ if the cassette character is not the same as the memory character. Otherwise data will be read until ten successive zeroes are found. This sequence of zeroes is composed of the last program line end of line character, the end link and the seven terminator zeroes added by "CSAVE". Note that the routine will probably terminate during this sequence, when used by "CLOAD?", as memory comparison is still in progress. This accounts for the rather peculiar coding of the "CLOAD?" handler terminating conditions.

Address... 7182H

This table is used by the dispatcher when decoding function codes for the GRP device. It contains the address of the handler for each of the function codes, most are in fact error generators:

TO	FUNCTION
71B6H	0, open
71C2H	2, close
6E86H	4, random
7196H	6, sequential output
475AH	8, sequential input
475AH	10, loc
475AH	12, lof
475AH	14, eof
475AH	16, fpos
475AH	18, putback

Address... 7196H

This is the dispatcher sequential output routine for the GRP device. SCRMOD is first checked and an "Illegal function call" error generated (475AH) if the screen is in either text mode. The character to output is taken from register C and control transfers to the GRPPRT standard routine.

Address... 71A2H

This table is used by the DEVICE DISPATCHER when decoding function codes for the CRT device. It contains the address of the handler for each of the function codes, most are in fact

5. ROM BASIC INTERPRETER

error generators:

```
TO      FUNCTION
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
71B6H   0, open
71C2H   2, close
6E86H   4, random
71C3H   6, sequential output
475AH   8, sequential input
475AH  10, loc
475AH  12, lof
475AH  14, eof
475AH  16, fpos
475AH  18, putback
```

Address... 71B6H

This is the dispatcher open routine for the CRT, LPT and GRP devices. The required mode, in register E, is checked and a "Bad file name" error generated (6E6BH) for input or append. The FCB address is then placed in PTRFIL, the mode in byte 0 of the FCB and the routine terminates. Note that the Z80 RET instruction at the end of this routine (71C2H) is the dispatcher close routine for the CRT, LPT and GRP devices.

Address... 71C3H

This is the dispatcher sequential output routine for the CRT device. The character to output is taken from register C and control transfers to the CHPUT standard routine.

Address... 71C7H

This table is used by the dispatcher when decoding function codes for the CAS device. It contains the address of the handler for each of the function codes, several are error generators:

```
TO      FUNCTION
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
71DBH   0, open
7205H   2, close
6E86H   4, random
722AH   6, sequential output
723FH   8, sequential input
475AH  10, loc
475AH  12, lof
726DH  14, eof
475AH  16, fpos
727CH  18, putback
```

Address... 71DBH

This is the dispatcher open routine for the CAS device. The

5. ROM BASIC INTERPRETER

current I/O buffer position, held in byte 6 of the FCB, and CASPRV, which holds any putback character are both zeroed. The required mode, supplied in register E, is examined and a "Bad file name" error generated (6E6BH) for append or random modes. For output mode the identification block is then written to cassette (7125H) while for input mode the correct identification block is located on the cassette (70B8H). The FCB address is then placed in PTRFIL, the mode in byte 0 of the FCB and the routine terminates.

Address... 7205H

This is the dispatcher close routine for the CAS device. Byte 0 of the FCB is examined and, if the mode is input, CASPRV is zeroed and the routine terminates. Otherwise the remainder of the I/O buffer is filled with end of file characters (1AH) and the I/O buffer contents written to cassette (722FH). CASPRV is then zeroed and the routine terminates.

Address... 722AH

This is the dispatcher sequential output routine for the CAS device. The character to output is taken from register C and placed in the next free position in the I/O buffer (728BH). Byte 6 of the FCB, the I/O buffer position, is then incremented. If the I/O buffer position has wrapped round to zero this means that there are two hundred and fifty-six characters in the I/O buffer and it has to be written to cassette. The cassette motor is turned on, a short header is written to cassette (72F8H) followed by the I/O buffer contents (72DEH), and the motor is turned off via the TAPOOF standard routine.

Address... 723FH

This is the dispatcher sequential input routine for the CAS device. CASPRV is first checked (72BEH) to determine whether it contains a character which has been putback, in which case its contents will be non-zero. If so the routine terminates with the character in register A. Otherwise the I/O buffer position is checked (729BH) to determine whether it contains any characters. If the I/O buffer is empty the cassette motor is turned on and the header located (72E9H). Two hundred and fifty-six characters are then read in (72D4H), the cassette motor turned off via the TAPION standard routine and the I/O buffer position reset to zero. The character is then taken from the current I/O buffer position and the position incremented. Finally the character is checked to see if it is the end of file character (1AH). If it is not the routine terminates with the character in register A and FLAG NC. Otherwise the end of file character is placed in CASPRV, so that succeeding sequential input requests will always return the end of file condition, and the routine terminates with FLAG C.

5. ROM BASIC INTERPRETER

Address... 726DH

This is the dispatcher eof routine for the CAS device. The next character is input (723FH) and placed in CASPRV. It is then tested for the end of file code (1AH) and the result placed in DAC as an integer, zero for false, FFFFH for true.

Address... 727CH

This is the dispatcher putback routine for the CAS device. The character is simply placed in CASPRV to be picked up at the next sequential input request.

Address... 7281H

This routine is used by the dispatcher close function to check if there are any characters in the I/O buffer and then zero the I/O buffer position byte in the FCB.

Address... 728BH

This routine is used by the dispatcher sequential output function to place the character in register A in the I/O buffer at the current I/O buffer position, which is then incremented.

Address... 729BH

This routine is used by the dispatcher sequential input function to collect the character at the current I/O buffer position, which is then incremented.

Address... 72A6H

This table is used by the dispatcher when decoding function codes for the LPT device. It contains the address of the handler for each of the function codes, most are in fact error generators:

TO	FUNCTION
71B6H	0, open
71C2H	2, close
6E86H	4, random
72BAH	6, sequential output
475AH	8, sequential input
475AH	10, loc
475AH	12, lof
475AH	14, eof
475AH	16, fpos
475AH	18, putback

Address... 72BAH

This is the dispatcher sequential output routine for the LPT

5. ROM BASIC INTERPRETER

device. The character to output is taken from register C and control transfers to the OUTDLP standard routine.

Address... 72BEH

This routine is used by the dispatcher sequential input function to check if a putback character exists in CASPRV, and if not to return Flag Z. Otherwise CASPRV is zeroed and the character tested to see if it is the end of file character (1AH). If not it returns with the character in register A and FLAG NZ,NC. Otherwise the end of file character is placed back in CASPRV and the routine returns with FLAG Z,C.

Address... 72CDH

This routine is used by various dispatcher functions to check if the mode in register E is append, if so a "Bad file name" error is generated (6E6BH).

Address... 72D4H

This routine is used by various dispatcher functions to read a character from the cassette. The character is read via the TAPIN standard routine and a "Device I/O error" generated (73B2H) if FLAG C is returned.

Address... 72DEH

This routine is used by various dispatcher functions to write a character to cassette. The character is written via the TAPOUT standard routine and a "Device I/O error" generated (73B2H) if FLAG C is returned.

Address... 72E9H

This routine is used by various dispatcher functions to turn the cassette motor on for input. The motor is turned on via the TAPION standard routine and a "Device I/O error" generated (73B2H) if FLAG C is returned.

Address... 72F8H

This routine is used by various dispatcher functions to turn the cassette motor on for output, control simply transfers to the TAPOON standard routine.

Address... 7304H

This routine is used by the Interpreter Mainloop "OK" point, the "END" statement handler and the run-clear routine to shut down the printer. PRTFLG is first zeroed and then LPTPOS tested to see if any characters have been output but left hanging in the printer's line buffer. If so a CR,LF sequence is issued to flush the printer and LPTPOS zeroed.

5. ROM BASIC INTERPRETER

Address... 7323H

This routine issues a CR,LF sequence to the current output device via the OUTDO standard routine. LPTPOS or TTYPOS is then zeroed depending upon whether the printer or the screen is active.

Address... 7347H

This routine is used by the Factor Evaluator to apply the "INKEY\$" function. The state of the keyboard buffer is examined via the CHSNS standard routine. If the buffer is empty the address of a dummy null string descriptor is returned in DAC. Otherwise the next character is read from the keyboard buffer via the CHGET standard routine. After checking that sufficient space is available (6625H) the character is copied to the String Storage Area and the result descriptor created (6821H).

Address... 7367H

This routine is used by the "LIST" statement handler to output a character to the current output device via the OUTDO standard routine. If the character is a LF code then a CR code is also issued.

Address... 7374H

This routine is used by the Interpreter Mainloop to collect a line of text when input is from an I/O buffer rather than the keyboard, that is when a "LOAD" statement is active. Characters are sequentially input (6C71H) and placed in BUF until BUF fills up, a CR is detected or the end of file is reached. All characters are accepted apart from LF codes which are filtered out. If BUF fills up or a CR is detected the routine simply returns the line to the Mainloop. If the end of file is reached while some characters are in BUF the line is returned to the Mainloop. When end of file is reached with no characters in BUF then I/O buffer 0 is closed (6D7BH) and FILNAM checked to determine whether auto-run is required. If not control returns to the Interpreter "OK" point (411EH). Otherwise the system is cleared (629AH) and control transfers to the Runloop (4601H) to execute the program.

Address... 73B2H

This is the "Device I/O error" generator.

Address... 73B7H

This is the "MOTOR" statement handler. If no operand is present control transfers to the STMOTR standard routine with FFH in register A. If the "OFF" token (EBH) follows control transfers with 00H in register A. If the "ON" token (95H) follows control transfers with 01H in register A.

5. ROM BASIC INTERPRETER

Address... 73CAH

This is the "SOUND" statement handler. The register number operand, which must be less than fourteen, is evaluated (521CH) and placed in register A. The data operand is evaluated (521CH) and bit 7 set, bit 6 reset to avoid altering the PSG auxiliary I/O port modes' The data operand is placed in register E and control transfers to the WRTPSG standard routine.

Address... 73E4H

This is a single ASCII space used by the "PLAY" statement handler to replace a null string operand with a one character blank string.

Address... 73E5H

This is the "PLAY" statement handler. The address of the "PLAY" command table at 752EH is placed in MCLTAB for the macro language parser and PRSCNT zeroed. The first string operand, which is obligatory, is evaluated (4C64H), its storage freed (67D0H) and its length and address placed in VCBA at bytes 2, 3 and 4. The channel's stack pointer is initialized to VCBA+33 and placed in VCBA at bytes 5 and 6' If further text is present in the statement this process is repeated for voices B and C until a maximum of three operands have been evaluated, after this a "Syntax error" is generated (4055H). If there are less than three string operands present an end of queue mark (FFH) is placed in the queue (7507H) of each unused voice. Register A is then zeroed, to select voice A, and control drops into the play mainloop.

Address... 744DH

This is the play mainloop. The number of free bytes in the current queue is checked (7521H) and, if less than eight bytes remain, the next voice is selected (74D6H) to avoid waiting for the queue to empty. The remaining length of the operand string is then taken from the current voice buffer and, if zero bytes remain to be parsed, the loop again skips to the next voice (74D6H). Otherwise the current string length and address are taken from the voice buffer and placed in MCLLEN and MCLPTR for the macro language parser. The old stack contents are copied from the voice buffer to the Z80 stack (6253H), MCLFLG is made non-zero and control transfers to the macro language parser (56A2H).

The macro language parser will normally scan along the string, using the "PLAY" statement command handlers, until the string is exhausted. However, if a music queue fills up during note generation an abnormal termination is forced back to the play mainloop (748EH) so that the next voice can be processed without waiting for the queue to empty. When control returns normally an end of queue mark is placed in the current queue

5. ROM BASIC INTERPRETER

(7507H) and PRSCNT is incremented to show the number of strings completed. If control returns abnormally then anything left on the Z80 stack is copied into the current voice buffer (6253H). Because of the recursive nature of the macro language parser where the "X" command is involved there may be a number of four byte string descriptors, marking the point where the original string was suspended, left on the Z80 stack at termination. Saving the stack contents in the voice buffer means they can be restored when the loop gets around to that voice again. Note that as there are only sixteen bytes available in each voice buffer an "Illegal function call" error is generated (475AH) if too much data remains on the stack. This will occur when a queue fills up and multiple, nested "X" commands exist, for example:

```
10 A$="XB$;"
20 B$="XC$;"
30 C$="XD$;"
40 D$=STRING$(150,"A")
50 PLAY A$
```

There seems to be a slight bug in this section as only fifteen bytes of stack data are allowed, instead of sixteen, before an error is generated.

When control returns from the macro language parser register A is incremented to select the next voice for processing. When all three voices have been processed INTFLG is checked and, if CTRL-STOP has been detected by the interrupt handler, control transfers to the GICINI standard routine to halt all music and terminate. Assuming bit 7 of PRSCNT shows this to be the first pass through the mainloop, that is no voice has been temporarily suspended because of a full queue, PLYCNT is incremented and interrupt dequeuing started via the STRTMS standard routine. PRSCNT is then checked to determine the number of strings completed by the macro language parser. If all three operand strings have been completed the handler terminates, otherwise control transfers back to the start of the play mainloop to try each voice again.

Address... 7507H

This routine is used by the "PLAY" statement handler to place an end of queue mark (FFH) in the current queue via the PUTQ standard routine. If the queue is full it waits until space becomes available.

Address... 7521H

This routine is used by the "PLAY" statement handler to check how much space remains in the current queue via the LFTQ standard routine. If less than eight bytes remain (the largest possible music data packet is seven bytes long) FLAG C is returned.

5. ROM BASIC INTERPRETER

Address... 752EH

This table contains the valid command letters and associated addresses for the "PLAY" statement commands. Those commands which take a parameter, and consequently have bit 7 set in the table, are shown with an asterisk:

CMD	TO
ÄÄÄÄÄÄÄÄÄÄÄÄ

2283	...	G	48.997 Hz
2155	...	G+	51.908 Hz
2034	...	A	54.995 Hz
1920	...	A+	58.261 Hz
1812	...	B	61.773 Hz

Address... 7586H

This is the "PLAY" statement "V" command handler. The parameter, with a default value of eight, is placed in byte 18 of the current voice buffer without altering bit 6 of the existing contents. No music data is generated.

Address... 759EH

This is the "PLAY" statement "M" command handler. The parameter, with a default value of two hundred and fifty-five, is compared with the existing modulation period contained in bytes 19 and 20 of the current voice buffer. If they are the same the routine terminates with no action. Otherwise the new modulation period is placed in the voice buffer and bit 6 set in byte 18 of the voice buffer to indicate that the new value must be incorporated into the next music data packet produced. No music data is generated.

Address... 75BEH

This is the "PLAY" statement "S" command handler. The parameter is placed in byte 18 of the current voice buffer and bit 4 of the same byte set to indicate that the new value must be incorporated into the next music data packet produced. No music data is generated. Because of the PSG characteristics the shape and volume parameters are mutually exclusive so the same byte of the voice buffers is used for both.

Address... 75C8H

This is the "PLAY" statement "L" command handler. The parameter, with a default value of four, is placed in byte 16 of the current voice buffer where it is used in the computation of succeeding note durations. No music data is generated.

Address... 75E2H

This is the "PLAY" statement "T" command handler. The

5. ROM BASIC INTERPRETER

parameter, with a default value of one hundred and twenty, is placed in byte 17 of the current voice buffer where it will be used in the computation of succeeding note durations. No music data is generated.

Address... 75EFH

This is the "PLAY" statement "O" command handler. The parameter, with a default value of four, is placed in byte 15 of the current voice buffer where it is used in the computation of succeeding note frequencies. No music data is generated.

Address... 75FCH

This is the "PLAY" statement "R" command handler. The length parameter, with a default value of four, is left in register pair DE and a zero tone divider value placed in register pair HL. The existing volume value is taken from byte 18 of the current voice buffer, temporarily replaced with a zero value and control transferred to the note generator (769CH).

Address... 7621H

This is the "PLAY" statement "N" command handler. The obligatory parameter is first examined, if it is zero a rest is generated (760BH). If it is greater than ninety-six an "Illegal function call" error is generated (475AH). Otherwise twelve is repeatedly subtracted from the note number until underflow to obtain an octave number from one to nine in register E and a note number from zero to eleven in register C. Control then transfers to the note generator (7673H).

Address... 763EH

This is the "PLAY" statement "A" to "G" command handler. The note letter is first converted into a note number from zero to fourteen, this extended range being necessary because of the redundancy implicit in the notation. The table at 755FH is then used to obtain the offset into the tone divider table and the divider constant for the note placed in register pair DE. The octave value is taken from byte 15 of the current voice buffer and the divider constant halved until the correct octave is reached. The string operand is then examined directly (56EEH) to determine whether a trailing note length parameter exists. If so it is converted (572FH) and placed in register C. If no parameter exists the default length is taken from byte 16 of the current voice buffer. The duration of the note is then computed from:

$$\text{Duration (Interrupt ticks)} = 12,000 / (\text{LENGTH} * \text{TEMPO})$$

With the normal length value (4) and tempo value (120) this gives a note duration of twenty-five interrupt ticks of 20 ms each or 0.5 seconds. The string operand is then examined

5. ROM BASIC INTERPRETER

(56EEH) for trailing "." characters and, for each one, the duration multiplied by one and a half. Finally the resulting duration is checked and, if it is less than five interrupt ticks, it is replaced with a value of five. Thus the shortest note that can be generated on a UK machine is 0.10 seconds whatever the tempo or note length.

The music data packet, which will be three, five or seven bytes long, is then assembled in bytes 8 to 14 of the current voice buffer prior to placing it in the queue. The duration is placed in bytes 8 and 9 of the voice buffer. The volume and flag byte is taken from byte 18 and placed in byte 10 of the voice buffer with bit 7 set to indicate a volume change to the interrupt dequeuing routine. If bit 6 of the volume byte is set then the modulation period is taken from bytes 19 and 20 and added to the data packet at bytes 11 and 12. If the tone divider value is non-zero then it is added to the data packet at bytes 11 and 12 (without a modulation period) or bytes 13 and 14 (with a modulation period). Finally the byte count is mixed into the three highest bits of byte 8 of the voice buffer to complete the preparation of the music data packet.

If the tone divider value is zero, indicating a rest, the contents of SAVVOL are restored to byte 18 of the static buffer. The music data packet is then placed in the current queue via the PUTQ standard routine and the number of free bytes remaining checked (7521H). If less than eight bytes remain control transfers directly to the "PLAY" statement handler (748EH), otherwise control returns normally to the macro language parser.

Address... 7754H

This is the single precision constant 12,000 used in the computation of note duration.

Address... 7758H

This is the "PUT" statement handler. Register B is set to 80H and control drops into the "GET" statement handler.

Address... 775BH

This is the "GET" statement handler. Register B is zeroed, to distinguish "GET" from "PUT" and the next program token examined. Control then transfers to the "PUT SPRITE" statement handler (7AAFH) or the Disk BASIC "GET/PUT" statement handler (6C35H).

Address... 7766H

This is the "LOCATE" statement handler. If a column coordinate is present it is evaluated (521CH) and placed in register D, otherwise the current column is taken from CSRX. If

5. ROM BASIC INTERPRETER

a row coordinate is present it is evaluated (521CH) and placed in register E, otherwise the current row is taken from CSRY. If a cursor switch operand exists it is evaluated (521CH) and register A loaded with 78H for a zero operand (OFF) and 79H for any non-zero operand (ON). The cursor is then switched by outputting ESC, 78H/79H, "5" via the OUTDO standard routine. The row and column coordinates are placed in register pair HL and the cursor position set via the POSIT standard routine.

Address... 77A5H

This is the "STOP ON/OFF/STOP" statement handler. The address of the device's TRPTBL status byte is placed in register pair HL and control transfers to the "ON/OFF/STOP" routine (77CFH).

Address... 77ABH

This is the "SPRITE ON/OFF/STOP" statement handler. The address of the device's TRPTBL status byte is placed in register pair HL and control transfers to the "ON/OFF/STOP" routine (77CFH).

Address... 77B1H

This is the "INTERVAL ON/OFF/STOP" statement handler. As there is no specific "INTERVAL" token (control transfers here when an "INT" token is found) a check is first made on the program text for the characters "E" and "R" then the "VAL" token (94H). The address of the device's TRPTBL status byte is placed in register pair HL and control transfers to the "ON/OFF/STOP" routine (77CFH).

Address... 77BFH

This is the "STRIG ON/OFF/STOP" statement handler. The trigger number, from zero to four, is evaluated (7C08H) and the address of the device's TRPTBL status byte placed in register pair HL. The "ON/OFF/STOP" token is examined and the TRPTBL status byte modified accordingly (77FEH). Control then transfers directly to the Runloop (4612H) to avoid testing for pending interrupts until the end of the next statement.

Address... 77D4H

This is the "KEY(n) ON/OFF/STOP" statement handler. The key number, from one to ten, is evaluated (521CH) and the address of the devices' TRPTBL status byte placed in register pair HL. The "ON/OFF/STOP" token is examined and the TRPTBL status byte modified accordingly (77FEH). Bit 0 of the TRPTBL status byte, the ON bit, is then copied into the corresponding entry in FNKFLG for use during the interrupt keyscan and control transfers directly to the Runloop (4612H).

5. ROM BASIC INTERPRETER

Address... 77FEH

This routine checks for the presence of one of the interrupt switching tokens and transfers control to the appropriate routine: "ON" (631BH), "OFF" (632BH) or "STOP" (6331H). If no token is present a "Syntax error" is generated (4055H).

Address... 7810H

This routine is used by the "ON DEVICE GOSUB" statement handler (490DH) to check the program text for a device token. Unless none of the device tokens is present, in which case Flag C is returned, the device's TRPTBL entry number is returned in register B and the maximum allowable line number operand count in register C:

DEVICE	TRPTBL#	LINE NUMBERS
KEY	00	10
STOP	10	01
SPRITE	11	01
STRIG	12	05
INTERVAL	17	01

Additionally, for "INTERVAL" only, the interval operand is evaluated (542FH) and placed in INTVAL and INTCNT.

Address... 785CH

This routine is used by the "ON DEVICE GOSUB" statement handler (490DH) to place the address of a program line in TRPTBL. The TRPTBL entry number, supplied in register B, is multiplied by three and added to the table base to point to the relevant entry. The address, supplied in register pair DE, is then placed there LSB first, MSB second.

Address... 786CH

This is the "KEY" statement handler. If the following character is anything other than the "LIST" token (93H) control transfers to the "KEY n" statement handler (78AEH). Each of the ten function key strings is then taken from FNKSTR and displayed via the OUTDO standard routine with a CR,LF (7328H) after each one. The DEL character (7FH) or any control character smaller than 20H is replaced with a space.

Address... 78AEH

This is the "KEY n", "KEY(n) ON/OFF/STOP", "KEY ON" and "KEY OFF" statement handler. If the next program text character is "(" control transfers to the "KEY(n) ON/OFF/STOP" statement handler (77D4H). If it is an "ON" token (95H) control transfers to the DSPFNK standard routine and if it is an "OFF" token (EBH) to the ERAFNK standard routine. Otherwise the function

5. ROM BASIC INTERPRETER

key number is evaluated (521CH) and the key's FNKSTR address placed in register pair DE' The string operand is evaluated (4C64H) and its storage freed (67D0H)' Up to fifteen characters are copied from the string to FNKSTR and unused positions padded with zero bytes. If a zero byte is found in the operand string an "Illegal function call" error is generated (475AH). Control then transfers to the FNKSB standard routine to update the function key display if it is enabled.

Address... 7900H

This routine is used by the Factor Evaluator to apply the "TIME" function. The contents of JIFFY are placed in DAC as a single precision number (3236H).

Address... 790AH

This routine is used by the Factor Evaluator to apply the "CSRLIN" function. The contents of CSRY are decremented and placed in DAC as an integer (2E9AH).

Address... 7911H

This is the "TIME" statement handler. The operand is evaluated (542FH) and placed in JIFFY.

Address... 791BH

This routine is used by the Factor Evaluator to apply the "PLAY" function. The numeric channel selection operand is evaluated (7C08H). If this is zero the contents of MUSICF are placed in DAC as an integer of value zero or FFFFH. Otherwise the channel number is used to select the appropriate bit of MUSICF and this is then converted to an integer as before.

Address... 7940H

This routine is used by the Factor Evaluator to apply the "STICK" function to an operand contained in DAC. The stick number is checked (521FH) and passed to the GTSTCK standard routine in register A. The result is placed in DAC as an integer (4FCFH) .

Address... 794CH

This routine is used by the Factor Evaluator to apply the "STRIG" function to an operand contained in DAC. The trigger number is checked (521FH) and passed to the GTTRIG standard routine in register A. The result is placed in DAC as an integer of value zero or FFFFH.

Address... 795AH

This routine is used by the Factor Evaluator to apply the

5. ROM BASIC INTERPRETER

"PDL" function to an operand contained in DAC. The paddle number is checked (521FH) and passed to the GTPDL standard routine in register A. The result is placed in DAC as an integer (4FCFH).

Address... 7969H

This routine is used by the Factor Evaluator to apply the "PAD" function to an operand contained in DAC. The pad number is checked (521F) and passed to the GTPAD standard routine in register A. The result is placed in DAC as an integer for pads 1, 2, 5 or 6. For pads 0, 3, 4 or 7 the result is placed in DAC as an integer of value zero or FFFFH.

Address... 7980H

This is the "COLOR" statement handler. If a foreground colour operand exists it is evaluated (521CH) and placed in register E, otherwise the current foreground colour is taken from FORCLR. If a background colour operand exists it is evaluated (521CH) and placed in register D, otherwise the current background colour is taken from BAKCLR. If a border colour operand exists it is evaluated (521CH) and placed in BDRCLR. The foreground colour is placed in FORCLR and ATRBYT, the background colour in BAKCLR and control transfers to the CHGCLR standard routine to modify the VDP.

Address... 79CCH

This is the "SCREEN" statement handler. If a mode operand exists it is evaluated (521CH) and passed to the CHGMOD standard routine in register A. If a sprite size operand exists it is evaluated (521CH) and placed in bits 0 and 1 of RG1SAV, the Workspace Area copy of VDP Mode Register 1. The VDP sprite parameters are then cleared via the CLRSPR standard routine. If a key click operand exists it is evaluated (521CH) and placed in CLIKSW, zero to disable the click and non-zero to enable it. If a baud rate operand exists it is evaluated and the baud rate set (7A2DH). If a printer mode operand exists it is evaluated (521CH) and placed in NTMSXP, zero for an MSX printer and non-zero for a general purpose printer.

Address... 7A2DH

This routine is used to set the cassette baud rate. The operand is evaluated (521CH) and five bytes copied from CS1200 or CS2400 to LOW as appropriate.

Address... 7A48H

This is the "SPRITE" statement handler. If the next character is anything other than a "\$" control transfers to the "SPRITE ON/OFF/STOP" statement handler (77ABH). SCRMOD is then checked and an "Illegal function call" error generated (475AH)

5. ROM BASIC INTERPRETER

if the screen is in 40x24 Text Mode. The sprite pattern number is evaluated and its location in the VRAM Sprite Pattern Table obtained (7AA0H). The string operand is then evaluated (4C5FH) and its storage freed (67D0H). The sprite size, obtained via the GSPSIZ standard routine, is compared with the string length and, if the string is shorter than the sprite, the Sprite Pattern Table entry is first filled with zeroes via the FILVRM standard routine. Characters are then copied from the string body to the Sprite Pattern Table via the LDIRVM standard routine until the string is exhausted or the sprite is full. If the string is longer than the sprite size any excess characters are ignored.

Address... 7A84H

This routine is used by the Factor Evaluator to apply the "SPRITE\$" function. The sprite pattern number is evaluated and its location in the VRAM Sprite Pattern Table obtained (7A9FH). The sprite size, obtained via the GSPSIZ standard routine, is then placed in register pair BC to control the number of bytes copied. After checking that sufficient space is available in the String Storage Area (6627H) the sprite pattern is copied from VRAM via the LDIRMV standard routine and the result descriptor created (6654H). Note that as no check is made on the screen mode during this function some interesting side effects can be found, see below.

Address... 7A9FH

This routine is used by the "SPRITE\$" statement and function to locate a sprite pattern in the VRAM Sprite Pattern Table. The pattern number operand is evaluated (7C08H) and passed to the CALPAT standard routine in register A. The pattern address is placed in register pair DE and the routine terminates.

Note that no check is made on the pattern number magnitude for differing sprite sizes. Pattern numbers up to two hundred and fifty-five are accepted even in 16x16 sprite mode when the maximum pattern number should be sixty-three. As a result VRAM addresses greater than 3FFFH will be produced which will wrap around into low VRAM. With the "SPRITE\$" statement this will corrupt the Character Generator Table, for example:

```
10 SCREEN 3,2
20 SPRITE$(0)=STRING$(32,255)
30 PUT SPRITE 0,(0,0), ,0
40 SPRITE$(65)=STRING$(32,255)
50 GOTO 50
```

The above puts a real sprite in the top left of the screen and then uses an illegal statement in line 40 to corrupt the VRAM just to the right of it. The "SPRITE\$" function can also be manipulated in this way and, as there is no screen mode check, up to thirty-two bytes of the Name Table can be read in 40x24

5. ROM BASIC INTERPRETER

Text Mode, for example:

```
10 SCREEN 0,2
20 PRINT"something"
30 A$=SPRITE$(64)
40 PRINT A$
```

Address... 7AAFH

This is the "GET/PUT SPRITE" statement handler, control is transferred here from the general "GET/PUT" statement handler (775BH). Register B is first checked to make sure that the statement is "PUT" and an "Illegal function call" error generated (475AH) if otherwise. SCRMOD is then checked and an "Illegal function call" error generated (475AH) if the screen is in 40x24 Text Mode. The sprite number operand, from zero to thirty-one, is evaluated (521CH) and passed to the CALATR standard routine to locate the four byte attribute block in the Sprite Attribute Table. If a coordinate operand exists it is evaluated and the X coordinate placed in register pair BC, the Y coordinate in register pair DE (579CH).

The Y coordinate LSB is written to byte 0 of the attribute block in VRAM via the WRTVRM standard routine. Bit 7 of the X coordinate is then examined to determine whether it is negative, that is off the left hand side of the screen. If so thirty two is added to the X coordinate and register B is set to 80H to set the early clock bit in the attribute block. For example an X coordinate of -1 (FFFFH) would be changed to +31 with an early clock. The X coordinate LSB is then written to byte 1 of the attribute block via the WRTVRM standard routine. Byte 3 of the attribute block is read in via the RDVRM standard routine, the new early clock bit is mixed in and it is then written back to VRAM via the WRTVRM standard routine.

If a colour operand is present it is evaluated (521CH), byte 3 of the attribute block is read in via the RDVRM standard routine the new colour code is mixed into the lowest four bits and it is written back to VRAM via the WRTVRM standard routine. If a pattern number operand exists it is evaluated (521CH) and checked for magnitude against the current sprite size provided by the GSPSIZ standard routine. The maximum allowable pattern number is two hundred and fifty-five for 8x8 sprites and sixty-three for 16x16 sprites. The pattern number is written to byte 2 of the attribute block via the WRTVRM standard routine and the handler terminates.

Address... 7B37H

This is the "VDP" statement handler. The register number operand, from zero to seven, is evaluated (7C08H) followed by the data operand (521CH). The register number is placed in register C, the data value in register B and control transferred to the WRTVDP standard routine.

5. ROM BASIC INTERPRETER

Address... 7B47H

This routine is used by the Factor Evaluator to apply the "VDP" function. The register number operand, from zero to eight, is evaluated (7C08H) and added to RGOSAV to locate the corresponding register image in the Workspace Area. The VDP register image is then read and placed in DAC as an integer (4FCFH).

Address... 7B5AH

This is the "BASE" statement handler. The VDP table number operand, from zero to nineteen, is evaluated (7C08H) followed by the base address operand (4C64H). After checking that the base address is less than 4000H (7BFEH) the VDP table number is used to locate the associated entry in the masking table at 7BA3H. The base address is ANDed with the mask and an "Illegal function call" error generated (475AH) if any illegal bits are set. The VDP table number is then added to TXTNAM to locate the current base address in the Workspace Area and the new base address placed there. The VDP table number is divided by five to determine which of the four screen modes the table belongs to. If this is the same as the current screen mode the new base address is also written to the VDP (7B99H).

Address... 7B99H

This routine is used by the "BASE" statement handler to update the VDP base addresses. The current screen mode, in register A, is examined and control transfers to the SETTXT, SETT32, SETGRP or SETMLT standard routine as appropriate. Note that this is not a full VDP initialization and that the four current table addresses (NAMBAS, CGPBAS, PATBAS and ATRBAS) which are the ones actually used by the screen routines, are not updated. This can be demonstrated with the following, where the Interpreter carries on outputting to the old VRAM Name Table:

```
10 SCREEN 0
20 BASE(0)=&H400
30 PRINT"something"
40 FOR N=1 TO 2000:NEXT
50 BASE(0)=0
```

Note also that this routine contains a bug. While SETTXT is correctly used for 40x24 Text Mode, SETGRP is used for 32x24 Text Mode and SETMLT for Graphics Mode and Multicolour Mode. Any "BASE" statement should therefore be immediately followed by a "SCREEN" statement to perform a full initialization.

Address... 7BA3H

This masking table is used by the "BASE" statement handler to ensure that only legal VDP base addresses are accepted. The

5. ROM BASIC INTERPRETER

table number and corresponding Workspace Area variable are shown with each mask:

MASK	TABLE
03FFH	00, TXTNAM
003FH	01, TXTCOL
07FFH	02, TXTCGP
007FH	03, TXTATR
07FFH	04, TXTPAT
03FFH	05, T32NAM
003FH	06, T32COL
07FFH	07, T32CGP
007FH	08, T32ATR
07FFH	09, T32PAT
03FFH	10, GRPNAM
1FFFH	11, GRPCOL
1FFFH	12, GRPCGP
007FH	13, GRPATR
07FFH	14, GRPPAT
03FFH	15, MLTNAM
003FH	16, MLTCOL
07FFH	17, MLTCGP
007FH	18, MLTATR
07FFH	19, MLTPAT

Address... 7BCBH

This routine is used by the Factor Evaluator to apply the "BASE" function. The VDP table number operand, from zero to nineteen, is evaluated (7C08H) and added to TXTNAM to locate the required Workspace Area base address. This is then placed in DAC as a single precision number (3236H).

Address... 7BE2H

This is the "VPOKE" statement handler. The VRAM address operand is evaluated (4C64H) and checked to ensure that it is less than 4000H (7BFEH). The data operand is then evaluated (521CH) and passed to the WRTVRM standard routine in register A to write to the required address.

Address... 7BF5H

This routine is used by the Factor Evaluator to apply the "VPEEK" function to an operand contained in DAC. The VRAM address operand is checked to ensure it is less than 4000H (7BFEH). VRAM is then read via the RDVRM standard routine and the result placed in DAC as an integer (4FCFH).

Address... 7BFEH

This routine converts a numeric operand in DAC to an integer (2F8AH) and places it in register pair HL. If the operand is

5. ROM BASIC INTERPRETER

equal to or greater than 4000H, and thus outside the allowable VRAM range, an "Illegal function call" error is generated (475AH).

Address... 7C08H

This routine evaluates (521CH) a parenthesized numeric operand and returns it as an integer in register A. If the operand is greater than the maximum allowable value initially supplied in register A an "Illegal function call" error is generated (475AH).

Address... 7C16H

This is the "DSKO\$" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C1BH

This is the "SET" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C20H

This is the "NAME" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C25H

This is the "KILL" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C2AH

This is the "IPL" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C2FH

This is the "COPY" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C34H

This is the "CMD" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C39H

This routine is used by the Factor Evaluator to apply the "DSKF" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

5. ROM BASIC INTERPRETER

Address... 7C3EH

This routine is used by the Factor Evaluator to apply the "DSKI\$" function. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C43H

This routine is used by the Factor Evaluator to apply the "ATTR\$" function. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C48H

This is the "LSET" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C4DH

This is the "RSET" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine. L

Address... 7C52H

This is the "FIELD" statement handler. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C57H

This routine is used by the Factor Evaluator to apply the "MKI\$" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C5CH

This routine is used by the Factor Evaluator to apply the "MKS\$" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C61H

This routine is used by the Factor Evaluator to apply the "MKD\$" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C66H

This routine is used by the Factor Evaluator to apply the "CVI" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

5. ROM BASIC INTERPRETER

Address... 7C6BH

This routine is used by the Factor Evaluator to apply the "CVS" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C70H

This routine is used by the Factor Evaluator to apply the "CVD" function to an operand contained in DAC. An "Illegal function call" error is generated (475AH) on a standard MSX machine.

Address... 7C76H

This routine completes the power-up initialization. At this point the entire Workspace Area is zeroed and only EXPTBL and SLTTBL have been initialized. A temporary stack is set at F376H and all one hundred and twelve hooks (560 bytes) filled with Z80 RET opcodes (C9H). HIMEM is set to F380H and the lowest RAM location found (7D5DH) and placed in BOTTOM. The one hundred and forty-four bytes of data commencing at 7F27H are copied to the Workspace Area from F380H to F40FH. The function key strings are initialized via the INIFNK standard routine, ENDBUF and NLONLY are zeroed and a comma is placed in BUFMIN and a colon in KBFMIN. The address of the MSX ROM character set is taken from locations 0004H and 0005H and placed in CGPNT+1 and PRMPRV is set to point to PRMSTK. Dummy values are placed in STKTOP, MEMSIZ and VARTAB (their correct values are not known yet), one I/O buffer is allocated (7E6BH) and the Z80 SP set (62E5H). A zero byte is placed at the base of RAM, TXTTAB is set to the following location and a "NEW" executed (6287H).

The VDP is then initialized via the INITIO, INIT32 and CLRSPR standard routines, the cursor coordinates are set to row 11, column 10 and the sign on message "MSX system etc." is displayed (6678H). After a three second delay a search is carried out for any extension ROMs (7D75H) and a further "NEW" executed (6287H) in case a BASIC program has been run from ROM.

Finally the identification message "MSX BASIC etc." is displayed (7D29H) and control transfers to the Interpreter Mainloop "OK" point 411FH.

Address... 7D29H

This routine is used during power-up to enable the function key display, place the screen in 40x24 Text Mode via the INITXT standard routine, and display (6678H) the identification message "MSX BASIC etc.". The amount of free memory is then computed by subtracting the contents of VARTAB from the contents of STKTOP and displayed (3412H) followed by the "Bytes free" message.

5. ROM BASIC INTERPRETER

Address... 7E1AH

This routine is used to read two bytes from successive locations in an extension ROM. The initial address is supplied in register pair HL and the Slot ID in register C. The bytes are read via the RDSLT standard routine and returned in register pair DE. If both are zero FLAG Z is returned.

Address... 7E2AH

This routine converts the SLTATR position supplied in register B into the corresponding Slot ID in register C and ROM base address in register H. The position is first modified so that it runs from 0 to 63 rather than from 64 to 1, so that the required information is present in the form:

Figure 49

Bits 0 and 1 are shifted into the highest two bits of register H to form the address. Bits 4 and 5 are shifted to bits 0 and 1 of register C to form the Primary Slot number. Bits 2 and 3 are shifted to bits 2 and 3 of register C to form the Secondary Slot number and bit 7 of the corresponding EXPTBL entry copied to bit 7 of register C.

Address... 7E4BH

This is the "MAXFILES" statement handler. As control transfers here when a "MAX" token (CDH) is detected the program text is first checked for a trailing "FILES" token (B7H). The buffer count operand, from zero to fifteen, is then evaluated (521CH) and any existing buffers closed (6C1CH). The required number of I/O buffers are allocated (7E6BH), the system is cleared (62A7H) and control transfers directly to the Runloop (4601H).

Address... 7E6BH

This is the I/O buffer allocation routine. It is used during power-up and by the "MAXFILES" and "CLEAR" statement handlers to allocate storage for the number of I/O buffers supplied in register A. Two hundred and sixty-seven bytes are subtracted from the contents of HIMEM for every buffer to produce a new MEMSIZ value. The size of the existing String Storage Area (initially two hundred bytes) is computed by subtracting the old contents of STKTOP from the old contents of MEMSIZ, this is then subtracted from the new MEMSIZ value to produce the new STKTOP value. A further one hundred and forty bytes are

5. ROM BASIC INTERPRETER

subtracted for the Z80 stack and an "Out of memory" error generated (6275H) if this address is lower than the start of the Variable Storage Area. Otherwise the buffer count is placed in MAXFIL and MEMSIZ and STKTOP set to their new values. The caller's return address is popped, the Z80 SP set to the new position and the return address pushed back onto the stack. FILTAB is then set to the start of the I/O buffer pointer block and each pointer set to point to the associated FCB. Finally the address of I/O buffer 0, the Interpreter's "LOAD" and "SAVE" buffer, is placed in NULBUF and the routine terminates.

Address... 7ED8H

This is the plain text message "MSX system" terminated by a zero byte

Address... 7EE4H

This is the plain text message "version 1.0" CR,LF terminated by a zero byte.

Address... 7EF2H

This is the plain text message "MSX BASIC " terminated by a zero byte.

Address... 7EFDH

This is the plain text message "Copyright 1983 by Microsoft" CR,LF terminated by a zero byte.

Address... 7F1BH

This is the plain text message " Bytes free" terminated by a zero byte.

Address... 7F27H

This block of one hundred and forty-four data bytes is used to initialize the Workspace Area from F380H to F40FH.

Address... 7FB7H

This seven byte patch fixes a bug in the external device parsing routine (55F8H). It checks for a zero length device name in register A and changes it to one if necessary.

Address... 7FBEH

This section of the ROM is unused and filled with zero bytes.

6. MEMORY MAP

Workspace Area

The section of the Workspace Area from F380H to FD99H holds the BIOS/Interpreter variables. These are listed on the following pages in standard assembly language form:

```
F380H RDPRIM: OUT (0A8H),A ; Set new Primary Slot
F382H          LD E,(HL)   ; Read memory
F383H          JR WRPRM1   ; Restore old Primary Slot
```

This routine is used by the RDSLIT standard routine to switch Primary Slots and read a byte from memory. The new Primary Slot Register setting is supplied in register A, the old setting in register D and the byte read returned in register E.

```
F385H WRPRIM: OUT (0A8H),A ; Set new Primary Slot
F387H          LD (HL),E   ; Write to memory
F388H WRPRM1: LD A,D      ; Get old setting
F389H          OUT (0A8H),A ; Restore old Primary Slot
F38BH          RET
```

This routine is used by the WRSLIT standard routine to switch Primary Slots and write a byte to memory. The new Primary Slot Register setting is supplied in register A, the old setting in register D and the byte to write in register E.

```
F38CH CLPRIM: OUT (0A8H),A ; Set new Primary Slot
F38EH          EX AF,AF'   ; Swap to AF for call
F38FH          CALL CLPRM1 ; Do it
F392H          EX AF,AF'   ; Swap to AF
F393H          POP AF     ; Get old setting
F394H          OUT (0A8H),A ; Restore old Primary Slot
F396H          EX AF,AF'   ; Swap to AF
F397H          RET
F398H CLPRM1: JP (IX)
```

This routine is used by the CALSLIT standard routine to switch Primary Slots and call an address. The new Primary Slot Register setting is supplied in register A, the old setting on the Z80 stack and the address to call in register pair IX.

```
F39AH USRTAB: DEFW 475AH ; USR 0
F39CH          DEFW 475AH ; USR 1
F39EH          DEFW 475AH ; USR 2
F3A0H          DEFW 475AH ; USR 3
F3A2H          DEFW 475AH ; USR 4
F3A4H          DEFW 475AH ; USR 5
F3A6H          DEFW 475AH ; USR 6
F3A8H          DEFW 475AH ; USR 7
F3AAH          DEFW 475AH ; USR 8
F3ACH          DEFW 475AH ; USR 9
```

These ten variables contain the "USR" function addresses. Their values are set to the Interpreter "Illegal function call" error

6. MEMORY MAP

generator at power-up and thereafter only altered by the "DEFUSR" statement.

F3AEH LINL40: DEFB 37

This variable contains the 40x24 Text Mode screen width. Its value is set at power-up and thereafter only altered by the "WIDTH" statement.

F3AFH LINL32: DEFB 29

This variable contains the 32x24 Text Mode screen width. Its value is set at power-up and thereafter only altered by the "WIDTH" statement.

F3B0H LINLEN: DEFB 37

This variable contains the current text mode screen width. Its value is set from LINL40 or LINL32 whenever the VDP is initialized to a text mode via the INITXT or INIT32 standard routines.

F3B1H CRTCNT: DEFB 24

This variable contains the number of rows on the screen. Its value is set at power-up and thereafter unaltered.

F3B2H CLMLST: DEFB 14

This variable contains the minimum number of columns that must still be available on a line for a data item to be "PRINT"ed, if less space is available a CR,LF is issued first. Its value is set at power-up and thereafter only altered by the "WIDTH" and "SCREEN" statements.

F3B3H TXTNAM: DEFW 0000H ; Name Table Base
F3B5H TXTCOL: DEFW 0000H ; Colour Table Base
F3B7H TXTCGP: DEFW 0800H ; Character Pattern Base
F3B9H TXTATR: DEFW 0000H ; Sprite Attribute Base
F3BBH TXTPAT: DEFW 0000H ; Sprite Pattern Base

These five variables contain the 40x24 Text Mode VDP base addresses. Their values are set at power-up and thereafter only altered by the "BASE" statement.

F3BDH T32NAM: DEFW 1800H ; Name Table Base
F3BFH T32COL: DEFW 2000H ; Colour Table Base
F3C1H T32CGP: DEFW 0000H ; Character Pattern Base
F3C3H T32ATR: DEFW 1B00H ; Sprite Attribute Base
F3C5H T32PAT: DEFW 3800H ; Sprite Pattern Base

These five variables contain the 32x24 Text Mode VDP base addresses. Their values are set at power-up and thereafter only altered by the "BASE" statement.

6. MEMORY MAP

```
F3C7H GRPNAM: DEFW 1800H ; Name Table Base
F3C9H GRPCOL: DEFW 2000H ; Colour Table Base
F3CBH GRPCGP: DEFW 0000H ; Character Pattern Base
F3CDH GRPATR: DEFW 1B00H ; Sprite Attribute Base
F3CFH GRPPAT: DEFW 3800H ; Sprite Pattern Base
```

These five variables contain the Graphics Mode VDP base addresses. Their values are set at power-up and thereafter only altered by the "BASE" statement.

```
F3D1H MLTNAM: DEFW 0800H ; Name Table Base
F3D3H MLTCOL: DEFW 0000H ; Colour Table Base
F3D5H MLTCGP: DEFW 0000H ; Character Pattern Base
F3D7H MLTATR: DEFW 1B00H ; Sprite Attribute Base
F3D9H MLTPAT: DEFW 3800H ; Sprite Pattern Base
```

These five variables contain the Multicolour Mode VDP base addresses. Their values are set at power-up and thereafter only altered by the "BASE" statement.

```
F3DBH CLIKSW: DEFB 01H
```

This variable controls the interrupt handler key click: 00H=Off, NZ=On. Its value is set at power-up and thereafter only altered by the "SCREEN" statement.

```
F3DCH CSRY: DEFB 01H
```

This variable contains the row coordinate (from 1 to CTCNT) of the text mode cursor.

```
F3DDH CSRX: DEFB 01H
```

This variable contains the column coordinate (from 1 to LINLEN) of the text mode cursor. Note that the BIOS cursor coordinates for the home position are 1,1 whatever the screen width.

```
F3DEH CNSDFG: DEFB FFH
```

This variable contains the current state of the function key display: 00H=Off, NZ=On.

```
F3DFH RG0SAV: DEFB 00H
F3E0H RG1SAV: DEFB F0H
F3E1H RG2SAV: DEFB 00H
F3E2H RG3SAV: DEFB 00H
F3E3H RG4SAV: DEFB 01H
F3E4H RG5SAV: DEFB 00H
F3E5H RG6SAV: DEFB 00H
F3E6H RG7SAV: DEFB F4H
```

These eight variables mimic the state of the eight write-only VDP Mode Registers. The values shown are for 40x24 Text Mode.

6. MEMORY MAP

F3E7H STATFL: DEFB CAH

This variable is continuously updated by the interrupt handler with the contents of the VDP Status Register.

F3E8H TRGFLG: DEFB F1H

This variable is continuously updated by the interrupt handler with the state of the four joystick trigger inputs and the space key.

F3E9H FORCLR: DEFB 0FH ; White

This variable contains the current foreground colour. Its value is set at power-up and thereafter only altered by the "COLOR" statement. The foreground colour is used by the CLRSPR standard routine to set the sprite colour and by the CHGCLR standard routine to set the 1 pixel colour in the text modes. It also functions as the graphics ink colour as it is copied to ATRBYT by the GRPRT standard routine and used throughout the Interpreter as the default value for any optional colour operand.

F3EAH BAKCLR: DEFB 04H ; Dark blue

This variable contains the current background colour. Its value is set at power-up and thereafter only altered by the "COLOR" statement. The background colour is used by the CLS standard routine to clear the screen in the graphics modes and by the CHGCLR standard routine to set the 0 pixel colour in the text modes.

F3EBH BDRCLR: DEFB 04H ; Dark blue

This variable contains the current border colour. Its value is set at power-up and thereafter only altered by the "COLOR" statement. The border colour is used by the CHGCLR standard routine in 32x24 Text Mode, Graphics Mode and Multicolour Mode to set the border colour.

F3ECH MAXUPD: DEFB C3H
F3EDH DEFW 0000H

These two bytes are filled in by the "LINE" statement handler to form a Z80 JP to the RIGHTC, LEFTC, UPC or DOWNC standard routines.

F3EFH MINUPD: DEFB C3H
F3F0H DEFW 0000H

These two bytes are filled in by the "LINE" statement handler to form a Z80 JP to the RIGHTC, LEFTC, UPC or DOWNC standard routines.

6. MEMORY MAP

F3F2H ATRBYT: DEFB 0FH

This variable contains the graphics ink colour used by the SETC and NSETCX standard routines.

F3F3H QUEUES: DEFW F959H

This variable contains the address of the control blocks for the three music queues. Its value is set at power-up and thereafter unaltered.

F3F5H FRCNEW: DEFB FFH

This variable contains a flag to distinguish the two statements in the "CLOAD/CLOAD?" statement handler: 00H=CLOAD, FFH=CLOAD?.

F3F6H SCNCNT: DEFB 01H

This variable is used as a counter by the interrupt handler to control the rate at which keyboard scans are performed.

F3F7H REPCNT: DEFB 01H

This variable is used as a counter by the interrupt handler to control the key repeat rate.

F3F8H PUTPNT: DEFW FBF0H

This variable contains the address of the put position in KEYBUF.

F3FAH GETPNT: DEFW FBF0H

This variable contains the address of the get position in KEYBUF.

F3FCH	CS1200:	DEFB 53H	; LO cycle 1st half
F3FDH		DEFB 5CH	; LO cycle 2nd half
F3FEH		DEFB 26H	; HI cycle 1st half
F3FFH		DEFB 2DH	; HI cycle 2nd half
F400H		DEFB 0FH	; Header cycle count

These five variables contain the 1200 baud cassette parameters. Their values are set at power-up and thereafter unaltered.

F401H	CS2400:	DEFB 25H	; LO cycle 1st half
F402H		DEFB 2DH	; LO cycle 2nd half
F403H		DEFB 0EH	; HI cycle 1st half
F404H		DEFB 16H	; HI cycle 2nd half
F405H		DEFB 1FH	; Header cycle count

These five variables contain the 2400 baud cassette parameters. Their values are set at power-up and thereafter unaltered.

6. MEMORY MAP

```
F406H LOW:      DEFB 53H      ; LO cycle 1st half
F407H          DEFB 5CH      ; LO cycle 2nd half
F408H HIGH:    DEFB 26H      ; HI cycle 1st half
F409H          DEFB 2DH      ; HI cycle 2nd half
F40AH HEADER:  DEFB 0FH      ; Header cycle count
```

These five variables contain the current cassette parameters. Their values are set to 1200 baud at power-up and thereafter only altered by the "CSAVE" and "SCREEN" statements.

```
F40BH ASPCT1:  DEFW 0100H
```

This variable contains the reciprocal of the default "CIRCLE" aspect ratio multiplied by 256. Its value is set at power-up and thereafter unaltered.

```
F40DH ASPCT2:  DEFW 01C0H
```

This variable contains the default "CIRCLE" aspect ratio multiplied by 256. Its value is set at power-up and thereafter unaltered. The aspect ratio is present in two forms so that the "CIRCLE" statement handler can select the appropriate one immediately rather than needing to examine and possibly reciprocate it as is the case with an operand in the program text.

```
F40FH ENDPRG:  DEFB ":"
F410H          DEFB 00H
F411H          DEFB 00H
FE12H          DEFB 00H
F413H          DEFB 00H
```

These five bytes form a dummy program line. Their values are set at power-up and thereafter unaltered. The line exists in case an error occurs in the Interpreter Mainloop before any tokenized text is available in KBUF. If an "ON ERROR GOTO" is active at this time then it provides some text for the "RESUME" statement to terminate on.

```
F414H ERRFLG:  DEFB 00H
```

This variable is used by the Interpreter error handler to save the error number.

```
F415H LPTPOS:  DEFB 00H
```

This variable is used by the "LPRINT" statement handler to hold the current position of the printer head.

```
F416H PRTFLG:  DEFB 00H
```

This variable determines whether the OUTDO standard routine directs its output to the screen or to the printer: 00H=Screen, 01H=Printer.

6. MEMORY MAP

F417H NTMSXP: DEFB 00H

This variable determines whether the OUTDO standard routine will replace headered graphics characters directed to the printer with spaces: 00H=Graphics, NZ=Spaces. Its value is set at power-up and thereafter only altered by the "SCREEN" statement.

F418H RAWPRT: DEFB 00H

This variable determines whether the OUTDO standard routine will modify control and headered graphics characters directed to the printer: 00H=Modify, NZ=Raw. Its value is set at power-up and thereafter unaltered.

F419H VLZADR: DEFW 0000H

F41BH VLZDAT: DEFB 00H

These variables contain the address and value of any character temporarily removed by the "VAL" function.

F41CH CURLIN: DEFW FFFFH

This variable contains the current Interpreter line number. A value of FFFFH denotes direct mode.

F41EH KBFMIN: DEFB ":"

This byte provides a dummy prefix to the tokenized text contained in KBUF. Its function is similar to that of ENDPRG but is used for the situation where an error occurs within a direct statement.

F41FH KBUF: DEFS 318

This buffer contains the tokenized form of the input line collected by the Interpreter Mainloop. When a direct statement is executed the contents of this buffer form the program text.

F55DH BUFMIN: DEFB ", "

This byte provides a dummy prefix to the text contained in BUF. It is used to synchronize the "INPUT" statement handler as it starts to analyze the input text.

F55EH BUF: DEFS 259

This buffer contains the text collected from the console by the INLIN standard routine.

F661H TTYPOS: DEFB 00H

This variable is used by the "PRINT" statement handler to hold the current screen position (Teletype!).

6. MEMORY MAP

F662H DIMFLG: DEFB 00H

This variable is normally zero but is set by the "DIM" statement handler to control the operation of the variable search routine.

F663H VALTYP: DEFB 02H

This variable contains the type code of the operand currently contained in DAC: integer, 3=String, 4=Single Precision, 8=Double Precision.

F664H DORES: DEFB 00H

This variable is normally zero but is set to prevent the tokenization of unquoted keywords following a "DATA" token.

F665H DONUM: DEFB 00H

This variable is normally zero but is set when a numeric constant follows one of the keywords GOTO, GOSUB, THEN, etc., and must be tokenized to the special line number operand form.

F666H CONTXT: DEFW 0000H

This variable is used by the CHRGTTR standard routine to save the address of the character following a numeric constant in the program text.

F668H CONSAV: DEFB 00H

This variable is used by the CHRGTTR standard routine to save the token of a numeric constant found in the program text.

F669H CONTYP: DEFB 00H

This variable is used by the CHRGTTR standard routine to save the type of a numeric constant found in the program text.

F66AH CONLO: DEFS 8

This buffer is used by the CHRGTTR standard routine to save the value of a numeric constant found in the program text.

F672H MEMSIZ: DEFW F168H

This variable contains the address of the top of the String Storage Area. Its value is set at power-up and thereafter only altered by the "CLEAR" and "MAXFILES" statements.

F674H STKTOP: DEFW F0A0H

This variable contains the address of the top of the Z80 stack. Its value is set at power-up to MEMSIZ-200 and thereafter only

6. MEMORY MAP

altered by the "CLEAR" and "MAXFILES" statements.

F676H TXTTAB: DEFW 8001H

This variable contains the address of the first byte of the Program Text Area. Its value is set at power-up and thereafter unaltered.

F678H TEMPPT: DEFW F67AH

This variable contains the address of the next free location in TEMPST.

F67AH TEMPST: DEFS 30

This buffer is used to store string descriptors. It functions as a stack with string producers pushing their results and string consumers popping them.

F698H DSCTMP: DEFS 3

This buffer is used by the string functions to hold a result descriptor while it is being constructed.

F69BH FRETOP: DEFW F168H

This variable contains the address of the next free location in the String Storage Area. When the area is empty FRETOP is equal to MEMSIZ.

F69DH TEMP3: DEFW 0000H

This variable is used for temporary storage by various parts of the Interpreter.

F69FH TEMP8: DEFW 0000H

This variable is used for temporary storage by various parts of the Interpreter.

F6A1H ENDFOR: DEFW 0000H

This variable is used by the "FOR" statement handler to hold the end of statement address during construction of a parameter block.

F6A3H DATLIN: DEFW 0000H

This variable contains the line number of the current "DATA" item in the program text.

F6A5H SUBFLG: DEFB 00H

This variable is normally zero but is set by the "ERASE",

6. MEMORY MAP

"FOR", "FN" and "DEF FN" handlers to control the processing of subscripts by the variable search routine.

F6A6H FLGINP: DEFB 00H

This variable contains a flag to distinguish the two statements in the "READ/INPUT" statement handler: 00H=INPUT, NZ=READ.

F6A7H TEMP: DEFW 0000H

This variable is used for temporary storage by various parts of the Interpreter.

F6A9H PTRFLG: DEFB 00H

This variable is normally zero but is set if any line number operands in the Program Text Area have been converted to pointers.

F6AAH AUTFLG: DEFB 00H

This variable is normally zero but is set when "AUTO" mode is turned on.

F6ABH AUTLIN: DEFW 0000H

This variable contains the current "AUTO" line number.

F6ADH AUTINC: DEFW 0000H

This variable contains the current "AUTO" line number increment.

F6AFH SAVTXT: DEFW 0000H

This variable is updated by the Runloop at the start of every statement with the current location in the program text. It is used during error recovery to set ERRTXT for the "RESUME" statement handler and OLDTXT for the "CONT" statement handler.

F6B1H SAVSTK: DEFW F09EH

This variable is updated by the Runloop at the start of every statement with the current Z80 SP for error recovery purposes.

F6B3H ERRLIN: DEFW 0000H

This variable is used by the error handler to hold the line number of the program line generating an error.

F6B5H DOT: DEFW 0000H

This variable is updated by the Mainloop and the error handler with the current line number for use with the "." parameter.

6. MEMORY MAP

F6B7H ERRTXT: DEFW 0000H

This variable is updated from SAVTXT by the error handler for use by the "RESUME" statement handler.

F6B9H ONELIN: DEFW 0000H

This variable is set by the "ON ERROR GOTO" statement handler with the address of the program line to execute when an error occurs.

F6BBH ONEFLG: DEFB 00H

This variable is normally zero but is set by the error handler when control transfers to an "ON ERROR GOTO" statement. This is to prevent a loop developing if an error occurs inside the error recovery statements.

F6BCH TEMP2: DEFW 0000H

This variable is used for temporary storage by various parts of the Interpreter.

F6BEH OLDLIN: DEFW 0000H

This variable contains the line number of the terminating program line. It is set by the "END" and "STOP" statement handlers for use with the "CONT" statement.

F6C0H OLDTXT: DEFW 0000H

This variable contains the address of the terminating program statement.

F6C2H VARTAB: DEFW 8003H

This variable contains the address of the first byte of the Variable Storage Area.

F6C4H ARYTAB: DEFW 8003H

This variable contains the address of the first byte of the Array Storage Area.

F6C6H STREND: DEFW 8003H

This variable contains the address of the byte following the Array Storage Area.

F6C8H DATPTR: DEFW 8000H

This variable contains the address of the current "DATA" item in the program text.

6. MEMORY MAP

```
F6CAH DEFTBL: DEFB 08H ; A
F6CBH DEFB 08H ; B
F6CCH DEFB 08H ; C
F6CDH DEFB 08H ; D
F6CEH DEFB 08H ; E
F6CFH DEFB 08H ; F
F6D0H DEFB 08H ; G
F6D1H DEFB 08H ; H
F6D2H DEFB 08H ; I
F6D3H DEFB 08H ; J
F6D4H DEFB 08H ; K
F6D5H DEFB 08H ; L
F6D6H DEFB 08H ; M
F6D7H DEFB 08H ; N

F6D9H DEFB 08H ; P
F6DAH DEFB 08H ; Q
F6DBH DEFB 08H ; R
F6DCH DEFB 08H ; S
F6DDH DEFB 08H ; T
F6DEH DEFB 08H ; U
F6DFH DEFB 08H ; V
F6E0H DEFB 08H ; W
F6E1H DEFB 08H ; X
F6E2H DEFB 08H ; Y
F6E3H DEFB 08H ; Z
```

These twenty-six variables contain the default type for each group of BASIC Variables. Their values are set to double precision at power-up, "NEW" and "CLEAR" and thereafter altered only by the "DEF" group of statements.

```
F6E4H PRMSTK: DEFW 0000H
```

This variable contains the base address of the previous "FN" parameter block on the Z80 stack. It is used during string garbage collection to travel from block to block on the stack.

```
F6E6H PRMLen: DEFW 0000H
```

This variable contains the length of the current "FN" parameter block in PARM1.

```
F6E8H PARM1 : DEFS 100
```

This buffer contains the local Variables belonging to the "FN" function currently being evaluated.

```
F74CH PRMPRV: DEFW F6E4H
```

This variable contains the address of the previous "FN" parameter block. It is actually a constant used to ensure that string garbage collection commences with the current parameter block before proceeding to those on the stack.

6. MEMORY MAP

F74EH PRMLN2: DEFW 0000H

This variable contains the length of the "FN" parameter block being constructed in PARM2

F750H PARM2: DEFS 100

This buffer is used to construct the local Variables owned by the current "FN" function.

F7B4H PRMFLG: DEFB 00H

This variable is used during a Variable search to indicate whether local or global Variables are being examined.

F7B5H ARYTA2: DEFW 0000H

This variable is used during a Variable search to hold the termination address of the storage area being examined.

F7B7H NOFUNS: DEFB 00H

This variable is normally zero but is set by the "FN" function handler to indicate to the variable search routine that local Variables are present.

F7B8H TEMP9: DEFW 0000H

This variable is used for temporary storage by various parts of the Interpreter.

F7BAH FUNACT: DEFW 0000H

This variable contains the number of currently active "FN" functions.

F7BCH SWPTMP: DEFS 8

This buffer is used to hold the first operand in a "SWAP" statement.

F7C4H TRCFLG: DEFB 00H

This variable is normally zero but is set by the "TRON" statement handler to turn on the trace facility.

F7C5H FBUFFR: DEFS 43

This buffer is used to hold the text produced during numeric output conversion.

F7F0H DECTMP: DEFW 0000H

This variable is used for temporary storage by the double

6. MEMORY MAP

precision division routine.

F7F2H DECTM2: DEFW 0000H

This variable is used for temporary storage by the double precision division routine.

F7F4H DECCNT: DEFB 00H

This variable is used by the double precision division routine to hold the number of non-zero bytes in the mantissa of the second operand.

F7F6H DAC: DEFS 16

This buffer functions as the Interpreter's primary accumulator during expression evaluation.

F806H HOLD8: DEFS 65

This buffer is used by the double precision multiplication routine to hold the multiples of the first operand.

F847H ARG: DEFS 16

This buffer functions as the Interpreter's secondary accumulator during expression evaluation.

F857H RNDX: DEFS 8

This buffer contains the current double precision random number.

F85FH MAXFIL: DEFB 01H

This variable contains the number of currently allocated user I/O buffers. Its value is set to 1 at power-up and thereafter only altered by the "MAXFILES" statement.

F860H FILTAB: DEFW F16AH

This variable contains the address of the pointer table for the I/O buffer FCBS.

F862H NULBUF: DEFW F177H

This variable contains the address of the first byte of the data buffer belonging to I/O buffer 0.

F864H PTRFIL: DEFW 0000H

This variable contains the address of the currently active I/O buffer FCB.

6. MEMORY MAP

F866H FILNAM: DEFS 11

This buffer holds a user-specified filename. It is eleven characters long to allow for disc file specs such as "FILENAME.BAS".

F871H FILNM2: DEFS 11

This buffer holds a filename read from an I/O device for comparison with the contents of FILNAM.

F87CH NLONLY: DEFB 00H

This variable is normally zero but is set during a program "LOAD". Bit 0 is used to prevent I/O buffer 0 being closed during loading and bit 7 to prevent the user I/O buffers being closed if auto-run is required.

F87DH SAVEND: DEFW 0000H

This variable is used by the "BSAVE" statement handler to hold the end address of the memory block to be saved.

F87FH FNKSTR: DEFS 160

This buffer contains the ten sixteen-character function key strings. Their values are set at power-up and thereafter only altered by the "KEY" statement.

F91FH CGPNT: DEFB 00H ; Slot ID
F920H DEFW 1BBFH ; Address

These variables contain the location of the character set copied to the VDP by the INITXT and INIT32 standard routines. Their values are set to the MSX ROM character set at power-up and thereafter unaltered.

F922H NAMBAS: DEFW 0000H

This variable contains the current text mode VDP Name Table base address. Its value is set from TXTNAM or T32NAM whenever the VDP is initialized to a text mode via the INITXT or INIT32 standard routines.

F924H CGPBAS: DEFW 0800H

This variable contains the current text mode VDP Character Pattern Table base address. Its value is set from TXTCGP or T32CGP whenever the VDP is initialized to a text mode via the INITXT or INIT32 standard routines.

F926H PATBAS: DEFW 3800H

This variable contains the current VDP Sprite Pattern Table

6. MEMORY MAP

base address. Its value is set from T32PAT, GRPPAT or MLTPAT whenever the VDP is initialized via the INIT32, INIGRP or INIMLT standard routines.

F928H ATRBAS: DEFW 1B00H

This variable contains the current VDP Sprite Attribute Table base address. Its value is set from T32ATR, GRPATR or MLTATR whenever the VDP is initialized via the INIT32, INIGRP or INIMLT standard routines.

F92AH CLOC: DEFW 0000H ; Pixel location
F92CH CMASK: DEFB 80H ; Pixel Mask

These variables contain the current pixel physical address used by the RIGHTC, LEFTC, UPC, TUPC, DOWNC, TDOWNC, FETCHC, STOREC, READC, SETC, NSETCX, SCANR and SCANL standard routines. CLOC holds the address of the byte containing the current pixel and CMASK defines the pixel within that byte.

F92DH MINDEL: DEFW 0000H

This variable is used by the "LINE" statement handler to hold the minimum difference between the end points of the line.

F92FH MAXDEL: DEFW 0000H

This variable is used by the "LINE" statement handler to hold the maximum difference between the end points of the line.

F931H ASPECT: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the current aspect ratio. This is stored as a single byte binary fraction so an aspect ratio of 0.75 would become 00C0H. The MSB is only required if the aspect ratio is exactly 1.00, that is 0100H.

F933H CENCNT: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the point count of the end angle.

F935H CLINEF: DEFB 00H

This variable is used by the "CIRCLE" statement handler to hold the two line flags. Bit 0 is set if a line is required from the start angle to the centre and bit 7 set if one is required from the end angle.

F936H CNPNTS: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the number of points within a forty-five degree segment.

6. MEMORY MAP

F938H CPLOTF: DEFB 00H

This variable is normally zero but is set by the "CIRCLE" statement handler if the end angle is smaller than the start angle. It is used to determine whether the pixels should be set "inside" the angles or "outside" them.

F939H CPCNT: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the point count within the current forty-five degree segment, this is in fact the Y coordinate.

F93BH CPCNT8: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the total point count of the present position.

F93DH CRCSUM: DEFW 0000H

This variable is used by the "CIRCLE" statement handler as the point computation counter.

F93FH CSTCNT: DEFW 0000H

This variable is used by the "CIRCLE" statement handler to hold the point count of the start angle.

F941H CSCLXY: DEFB 00H

This variable is used by the "CIRCLE" statement handler as a flag to determine in which direction the elliptic squash is to be applied: 00H=Y, 01H=X.

F942H CSAVEA: DEFW 0000H

This variable is used for temporary storage by the SCANR standard routine.

F944H CSAVEM: DEFB 00h

This variable is used for temporary storage by the SCANR standard routine.

F945H CXOFF: DEFW 0000H

This variable is used for temporary storage by the "CIRCLE" statement handler.

F947H CYOFF: DEFW 0000H

This variable is used for temporary storage by the "CIRCLE" statement handler.

6. MEMORY MAP

F949H LOHMSK: DEFB 00H

This variable is used by the "PAINT" statement handler to hold the leftmost position of a LH excursion.

F94AH LOHDIR: DEFB 00H

This variable is used by the "PAINT" statement handler to hold the new paint direction required by a LH excursion.

F94BH LOHADR: DEFW 0000H

This variable is used by the "PAINT" statement handler to hold the leftmost position of a LH excursion.

F94DH LOHCNT: DEFW 0000H

This variable is used by the "PAINT" statement handler to hold the size of a LH excursion.

F94FH SKPCNT: DEFW 0000H

This variable is used by the "PAINT" statement handler to hold the skip count returned by the SCANR standard routine.

F951H MOVCNT: DEFW 0000H

This variable is used by the "PAINT" statement handler to hold the movement count returned by the SCANR standard routine.

F953H PDIREC: DEFB 00H

This variable is used by the "PAINT" statement handler to hold the current paint direction: 40H=Down, C0H=Up, 00H=Terminate.

F954H LFPROG: DEFB 00H

This variable is normally zero but is set by the "PAINT" statement handler if there has been any leftwards progress.

F955H RTPROG: DEFB 00H

This variable is normally zero but is set by the "PAINT" statement handler if there has been any rightwards progress.

F956H MCLTAB: DEFW 0000H

This variable contains the address of the command table to be used by the macro language parser. The "DRAW" table is at 5D83H and the "PLAY" table at 752EH.

F958H MCLFLG: DEFB 00H

This variable is zero if the macro language parser is being

6. MEMORY MAP

used by the "DRAW", statement handler and non-zero if it is being used by "PLAY".

```
F959H QUETAB: DEFB 00H      ; AQ Put position
F95AH          DEFB 00H      ; AQ Get position
F95BH          DEFB 00H      ; AQ Putback flag
F95CH          DEFB 7FH      ; AQ Size
F95DH          DEFW F975H    ; AQ Address

F95FH          DEFB 00H      ; BQ Put position
F960H          DEFB 00H      ; BQ Get position
F961H          DEFB 00H      ; BQ Putback flag
F962H          DEFB 7FH      ; BQ Size
F963H          DEFW F9F5H    ; BQ Address

F965H          DEFB 00H      ; CQ Put position
F966H          DEFB 00H      ; CQ Get position
F967H          DEFB 00H      ; CQ Putback flag
F968H          DEFB 7FH      ; CQ Size
F969H          DEFW FA75H    ; CQ Address

F96BH          DEFB 00H      ; RQ Put position
F96CH          DEFB 00H      ; RQ Get position
F96DH          DEFB 00H      ; RQ Putback flag
F96EH          DEFB 00H      ; RQ Size
F96FH          DEFW 0000H    ; RQ Address
```

These twenty-four variables form the control blocks for the three music queues (VOICAQ, VOICBQ and VOICCQ) and the RS232 queue. The three music control blocks are initialized by the GICINI standard routine and thereafter maintained by the interrupt handler and the PUTQ standard routine. The RS232 control block is unused in the current MSX ROM.

```
F971H QUEBAK: DEFB 00H      ; AQ Putback character
F972H          DEFB 00H      ; BQ Putback character
F973H          DEFB 00H      ; CQ Putback character
F974H          DEFB 00H      ; RQ Putback character
```

These four variables are used to hold any unwanted character returned to the associated queue. Although the putback facility is implemented in the MSX ROM it is currently unused.

```
F975H VOICAQ: DEFS 128      ; Voice A queue
F9F5H VOICBQ: DEFS 128      ; Voice B queue
FA75H VOICCQ: DEFS 128      ; Voice C queue
FAF5H RS2IQ:  DEFS 64       ; RS232 queue
```

These four buffers contain the three music queues and the RS232 queue, the latter is unused.

```
FB35H PRSCNT: DEFB 00H
```

This variable is used by the "PLAY" statement handler to count

6. MEMORY MAP

the number of completed operand strings. Bit 7 is also set after each of the three operands has been parsed to prevent repeated activation of the STRTMS standard routine.

FB36H SAVSP: DEFW 0000H

This variable is used by the "PLAY" statement handler to save the Z80 SP before control transfers to the macro language parser. Its value is compared with the SP on return to determine whether any data has been left on the stack because of a queue-full termination by the parser.

FB38H VOICEN: DEFB 00H

This variable contains the current voice number being processed by the "PLAY" statement handler. The values 0, 1 and 2 correspond to PSG channels A, B and C.

FB39H SAVVOL: DEFW 0000H

This variable is used by the "PLAY" statement "R" command handler to save the current volume setting while a zero-amplitude rest is generated.

FB3BH MCLLEN: DEFB 00H

This variable is used by the macro language parser to hold the length of the string operand being parsed.

FB3CH MCLPTR: DEFW 0000H

This variable is used by the macro language parser to hold the address of the string operand being parsed.

FB3EH QUEUEN: DEFB 00H

This variable is used by the interrupt handler to hold the number of the music queue currently being processed. The values 0, 1 and 2 correspond to PSG channels A, B and C.

FB3FH MUSICF: DEFB 00H

This variable contains three bit flags set by the STRTMS standard routine to initiate processing of a music queue by the interrupt handler. Bits 0, 1 and 2 correspond to VOICAQ, VOICBQ and VOICCQ.

FB40H PLYCNT: DEFB 00H

This variable is used by the STRTMS standard routine to hold the number of "PLAY" statement sequences currently held in the music queues. It is examined when all three end of queue marks have been found for one sequence to determine whether dequeuing should be restarted.

6. MEMORY MAP

```
FB41H VCBA:  DEFW 0000H  ; Duration counter
FB43H        DEFB 00H    ; String length
FB44H        DEFW 0000H  ; String address
FB46H        DEFW 0000H  ; Stack data address
FB48H        DEFB 00H    ; Music packet length
FB49H        DEFS 7      ; Music packet
FB50H        DEFB 04H    ; Octave
FB51H        DEFB 04H    ; Length
FB52H        DEFB 78H    ; Tempo
FB53H        DEFB 88H    ; Volume
FB54H        DEFW 00FFH  ; Envelope period
FB56H        DEFS 16     ; Space for stack data
```

This thirty-seven byte buffer is used by the "PLAY" statement handler to hold the current parameters for voice A.

```
FB66H VCBB:  DEFS 37
```

This buffer is used by the "PLAY" statement handler to hold the current parameters for voice B, its structure is the same as VCBA.

```
FB8BH VCBC:  DEFS 37
```

This buffer is used by the "PLAY" statement handler to hold the current parameters for voice C, its structure is the same as VCBA.

```
FBB0H ENSTOP: DEFB 00H
```

This variable determines whether the interrupt handler will execute a warm start to the Interpreter upon detecting the keys CODE, GRAPH, CTRL and SHIFT depressed together: 00H=Disable, NZ=Enable.

```
FBB1H BASROM: DEFB 00H
```

This variable determines whether the ISCNTC and INLIN standard routines will respond to the CTRL-STOP key: 00H=Enable, NZ=Disable. It is used to prevent termination of a BASIC ROM located during the power-up ROM search.

```
FBB2H LINTTB: DEFS 24
```

Each of these twenty-four variables is normally non-zero but is zeroed if the contents of the corresponding screen row have overflowed onto the next row. They are maintained by the BIOS but only actually used by the INLIN standard routine (the screen editor) to discriminate between logical and physical lines.

```
FBCAH FSTPOS: DEFW 0000H
```

This variable is used to hold the cursor coordinates upon entry

6. MEMORY MAP

to the INLIN standard routine. Its function is to restrict the extent of backtracking performed when the text is collected from the screen at termination.

FBCCH CURSAV: DEFB 00H

This variable is used to hold the screen character replaced by the text cursor.

FBCDH FNKSWI: DEFB 00H

This variable is used by the CHSNS standard routine to determine whether the shifted or unshifted function keys are currently displayed: 00H=Shifted, 01H=Unshifted.

FBCEH FNKFLG: DEFS 10

Each of these ten variables is normally zero but is set to 01H if the associated function key has been turned on by a "KEY(n) ON" statement. They are used by the interrupt handler to determine whether, in program mode only, it should return a character string or update the associated entry in TRPTBL.

FBD8H ONGSBF: DEFB 00H

This variable is normally zero but is incremented by the interrupt handler whenever a device has achieved the conditions necessary to generate a program interrupt. It is used by the Runloop to determine whether any program interrupts are pending without having to search TRPTBL.

FBD9H CLIKFL: DEFB 00H

This variable is used internally by the interrupt handler to prevent spurious key clicks when returning multiple characters from a single key depression such as a function key.

FBD9H OLDKEY: DEFS 11

This buffer is used by the interrupt handler to hold the previous state of the keyboard matrix, each byte contains one row of keys starting with row 0.

FBE5H NEWKEY: DEFS 11

This buffer is used by the interrupt handler to hold the current state of the keyboard matrix. Key transitions are detected by comparison with the contents of OLDKEY after which OLDKEY is updated with the current state.

FBF0H KEYBUF: DEFS 40

This buffer contains the decoded keyboard characters produced by the interrupt handler. Note that the buffer is organized as

6. MEMORY MAP

a circular queue driven by GETPNT and PUTPNT and consequently has no fixed starting point.

FC18H LINWRK: DEFS 40

This buffer is used by the BIOS to hold a complete line of screen characters.

FC40H PATWRK: DEFS 8

This buffer is used by the BIOS to hold an 8x8 pixel pattern.

FC48H BOTTOM: DEFW 8000H

This variable contains the address of the lowest RAM location used by the Interpreter. Its value is set at power-up and thereafter unaltered.

FC4AH HIMEM: DEFW F380H

This variable contains the address of the byte following the highest RAM location used by the Interpreter. Its value is set at power-up and thereafter only altered by the "CLEAR" statement.

FC4CH	TRPTBL:	DEFS 3	; KEY 1
FC4FH		DEFS 3	; KEY 2
FC52H		DEFS 3	; KEY 3
FC55H		DEFS 3	; KEY 4
FC58H		DEFS 3	; KEY 5
FC5BH		DEFS 3	; KEY 6
FC5EH		DEFS 3	; KEY 7
FC61H		DEFS 3	; KEY 8
FC64H		DEFS 3	; KEY 9
FC67H		DEFS 3	; KEY 10
FC6AH		DEFS 3	; STOP
FC6DH		DEFS 3	; SPRITE
FC70H		DEFS 3	; STRIG 0
FC73H		DEFS 3	; STRIG 1
FC76H		DEFS 3	; STRIG 2
FC79H		DEFS 3	; STRIG 3
FC7CH		DEFS 3	; STRIG 4
FC7FH		DEFS 3	; INTERVAL
FC82H		DEFS 3	; Unused
FC85H		DEFS 3	; Unused
FC88H		DEFS 3	; Unused
FC8BH		DEFS 3	; Unused
FC8EH		DEFS 3	; Unused
FC91H		DEFS 3	; Unused
FC94H		DEFS 3	; Unused
FC97H		DEFS 3	; Unused

These twenty-six three byte variables hold the current state of the interrupt generating devices. The first byte of each entry contains the device status (bit 0=On, bit 1=Stop, bit 2=Event

6. MEMORY MAP

active) and is updated by the interrupt handler, the Runloop interrupt processor and the "DEVICE 0=ON/OFF/STOP" and "RETURN" statement handlers. The remaining two bytes of each entry are set by the "ON DEVICE GOSUB" statement handler and contain the address of the program line to execute upon a program interrupt.

FC9AH RTYCNT: DEFB 00H

This variable is unused by the current MSX ROM.

FC9BH INTFLG: DEFB 00H

This variable is normally zero but is set to 03H or 04H if the CTRL-STOP or STOP keys are detected by the interrupt handler.

FC9CH PADY: DEFB 00H

This variable contains the Y coordinate of the last point detected by a touchpad.

FC9DH PADX: DEFB 00H

This variable contains the X coordinate of the last point detected by a touchpad.

FC9EH JIFFY: DEFW 0000H

This variable is continually incremented by the interrupt handler. Its value may be set or read by the "TIME" statement or function.

FCA0H INTVAL: DEFW 0000H

This variable holds the interval duration set by the "ON INTERVAL" statement handler.

FCA2H INTCNT: DEFW 0000H

This variable is continually decremented by the interrupt handler. When zero is reached its value is reset from INTVAL and, if applicable, a program interrupt generated. Note that this variable always counts irrespective of whether an "INTERVAL ON" statement is active.

FCA4H LOWLIM: DEFB 31H

This variable is used to hold the minimum allowable start bit duration as determined by the TAPION standard routine.

FCA5H WINWID: DEFB 22H

This variable is used to hold the LO/HI cycle discrimination duration as determined by the TAPION standard routine.

6. MEMORY MAP

FCA6H GRPHED: DEFB 00H

This variable is normally zero but is set to 01H by the CNVCHR standard routine upon detection of a graphic header code.

FCA7H ESCCNT: DEFB 00H

This variable is used by the CHPUT standard routine ESC sequence processor to count escape parameters.

FCA8H INSFLG: DEFB 00H

This variable is normally zero but is set to FFH by the INLIN standard routine when insert mode is on.

FCA9H CSRSW: DEFB 00H

If this variable is zero the cursor is only displayed while the CHGET standard routine is waiting for a keyboard character. If it is non-zero the cursor is permanently displayed via the CHPUT standard routine.

FCAAH CSTYLE: DEFB 00H

This variable determines the cursor style: 00H=Block, NZ=Underline.

FCABH CAPST: DEFB 00H

This variable is used by the interrupt handler to hold the current caps lock status: 00H=Off, NZ=On.

FCACH KANAST: DEFB 00H

This variable is used to hold the keyboard Kana lock status on Japanese machines and the DEAD key status on European machines.

FCADH KANAMD: DEFB 00H

This variable holds a keyboard mode on Japanese machines only.

FCAEH FLBMEM: DEFB 00H

This variable is set by the file I/O error generators but is otherwise unused.

FCAFH SCRMOD: DEFB 00H

This variable contains the current screen mode: 0=40x24 Text Mode, 1=32x24 Text Mode, 2=Graphics Mode, 3=Multicolour Mode.

FCB0H OLDSCR: DEFB 00H

This variable holds the screen mode of the last text mode set.

6. MEMORY MAP

FCB1H CASPRV: DEFB 00H

This variable is used to hold any character returned to an I/O buffer by the cassette putback function.

FCB2H BDRATR: DEFB 00H

This variable contains the boundary colour for the "PAINT" statement handler. Its value is set by the PNTINI standard routine and used by the SCANR and SCANL standard routines.

FCB3H GXPOS: DEFW 0000H

This variable is used for temporary storage of a graphics X coordinate.

FCB5H GYPOS: DEFW 0000H

This variable is used for temporary storage of a graphics Y coordinate.

FCB7H GRPACX: DEFW 0000H

This variable contains the current graphics X coordinate for the GRPPRT standard routine.

FCB9H GRPACY: DEFW 0000H

This variable contains the current graphics Y coordinate for the GRPPRT standard routine.

FCBBH DRWFLG: DEFB 00H

Bits 6 and 7 of this variable are set by the "DRAW" statement "N" and "B" command handlers to turn the associated mode on.

FCBCH DRWSCL: DEFB 00H

This variable is used by the "DRAW" statement "S" command handler to hold the current scale factor.

FCBDH DRWANG: DEFB 00H

This variable is used by the "DRAW" statement "A" command handler to hold the current angle.

FCBEH RUNBNF: DEFB 00H

This variable is normally zero but is set by the "BLOAD" statement handler when an auto-run "R" parameter is specified.

FCBFH SAVENT: DEFW 0000H

This variable contains the "BSAVE" and "BLOAD" entry address.

6. MEMORY MAP

```
FCC1H EXPTBL: DEFB 00H      ; Primary Slot 0
FCC2H          DEFB 00H      ; Primary Slot 1
FCC3H          DEFB 00H      ; Primary Slot 2
FCC4H          DEFB 00H      ; Primary Slot 3
```

Each of these four variables is normally zero but is set to 80H during the power-up RAM search if the associated Primary Slot is found to be expanded.

```
FCC5H SLTTBL: DEFB 00H      ; Primary Slot 0
FCC6H          DEFB 00H      ; Primary Slot 1
FCC7H          DEFB 00H      ; Primary Slot 2
FCC8H          DEFB 00H      ; Primary Slot 3
```

These four variables duplicate the contents of the four possible Secondary Slot Registers. The contents of each variable should only be regarded as valid if EXPTBL shows the associated Primary Slot to be expanded.

```
FCC9H SLTATR: DEFS 4         ; PS0, SS0
FCCDH          DEFS 4         ; PS0, SS1
FCD1H          DEFS 4         ; PS0, SS2
FCD5H          DEFS 4         ; PS0, SS3

FCD9H          DEFS 4         ; PS1, SS0

FCE1H          DEFS 4         ; PS1, SS2
FCE5H          DEFS 4         ; PS1, SS3

FCE9H          DEFS 4         ; PS2, SS0
FCEDH          DEFS 4         ; PS2, SS1
FCF1H          DEFS 4         ; PS2, SS2
FCF5H          DEFS 4         ; PS2, SS3

FCF9H          DEFS 4         ; PS3, SS0
FCFDH          DEFS 4         ; PS3, SS1
FD01H          DEFS 4         ; PS3, SS2
FD05H          DEFS 4         ; PS3, SS3
```

These sixty-four variables contain the attributes of any extension ROMs found during the power-up ROM search. The characteristics of each 16 KB ROM are encoded into a single byte so four bytes are required for each possible slot. The encoding is:

```
Bit 7 set=BASIC program
Bit 6 set=Device handler
Bit 5 set=Statement handler
```

Note that the entries for page 0 (0000H to 3FFFH) and page 3 (C000H to FFFFH) will always be zero as only page 1 (4000H to 7FFFH) and page 2 (8000H to BFFFH) are actually examined. The MSX convention is that machine code extension ROMs are placed in page 1 and BASIC program ROMs in page 2.

6. MEMORY MAP

FD09H SLTWRK: DEFS 128

This buffer provides two bytes of local workspace for each of the sixty-four possible extension ROMs.

FD89H PROCNM: DEFS 16

This buffer is used to hold a device or statement name for examination by an extension ROM.

FD99H DEVICE: DEFB 00H

This variable is used to pass a device code, from 0 to 3, to an extension ROM.

The Hooks

The section of the Workspace Area from FD9AH to FFC9H contains one hundred and twelve hooks, each of which is filled with five Z80 RET opcodes at power-up. These are called from strategic locations within the BIOS/Interpreter so that the ROM can be extended, particularly so that it can be upgraded to Disk BASIC. Each hook has sufficient room to hold a far call to any slot:

```
RST 30H
  DEFB Slot ID
  DEFW Address
  RET
```

The hooks are listed on the following pages together with the address they are called from and a brief note as to their function.

FD9AH	HKEYI:	DEFS 5	; 0C4AH Interrupt handler
FD9FH	HTIMI:	DEFS 5	; 0C53H Interrupt handler
